BH/galaxy co-evolution: semi-analytic models (SAMs)

These follow the evolution and merging of Dark Matter Halos with cosmic time and use analytic recipes to treat baryon physics.

Ansatz:
nuclear trigger at merging

The merger-driven BH/galaxy evolutionary scheme

Can explain several observables:

- * local BH/galaxy scaling relations
- * local BH mass function
- * QSO luminosity function
- * QSO clustering
- * host galaxy colors

Hopkins+08

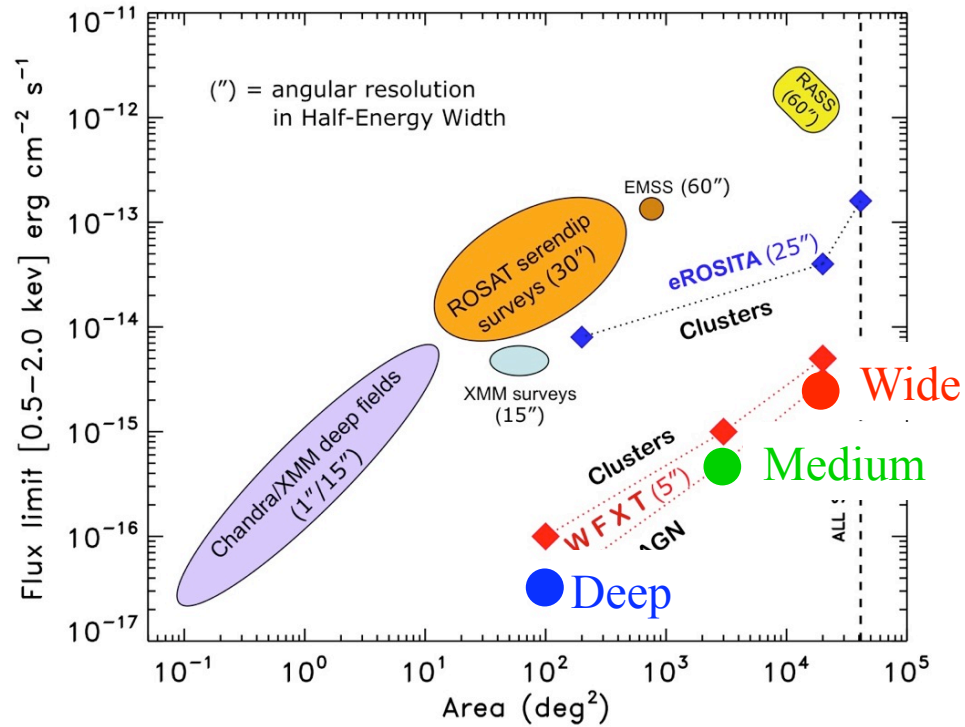

Missing pieces in BH/galaxy co-evolution

Many fundamental pieces missing:

- 1) BH/galaxy co-evolution at very high- z ($z > 6$ or so)
- 2) Cosmological evolution of obscuration
- 3) Environmental dependence of nuclear activity
→ Clustering as a function of AGN properties

These require sensitive large area X-ray surveys

AGN demography with WFXT

Wide $\sim 2000 \times$ XBootes $\sim 2000 \times 3300 \sim 6.6$ millions AGN

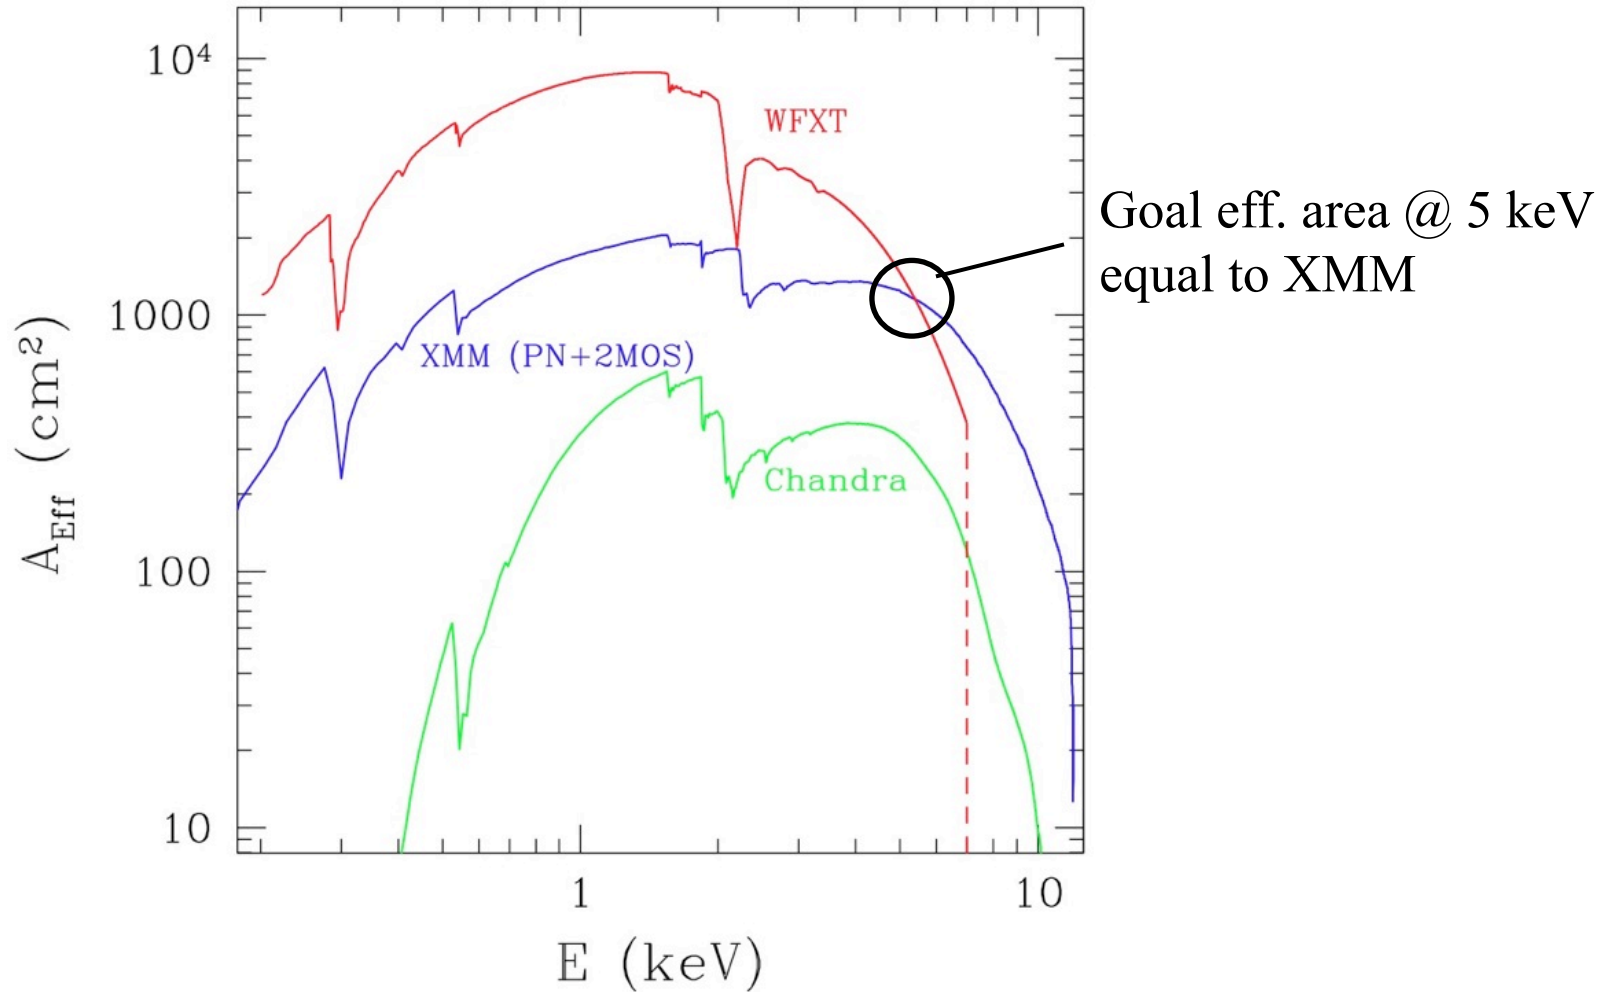

Medium $\sim 3000 \times$ C-Cosmos $\sim 3000 \times 1700 \sim 5.1$ millions AGN

Deep $\sim 1000 \times$ CDFS $\sim 1000 \times 450 \sim 0.5$ millions AGN

total > 10 millions AGN

Spectral characterization

WFXT does not really “die” at 4 keV.

AGN demography and spectral characterization

spectra $\rightarrow N_H$

AGN detections:

~15 millions 0.5-2 keV band

~4 millions 2-7 keV band

300,000 with good X-ray spectra:

>1000 cts 0.5-2 keV band

>1300 cts 0.5-7 keV band

\rightarrow Accurate N_H for very large sample

QSOs at $z > 6$: where do we stand

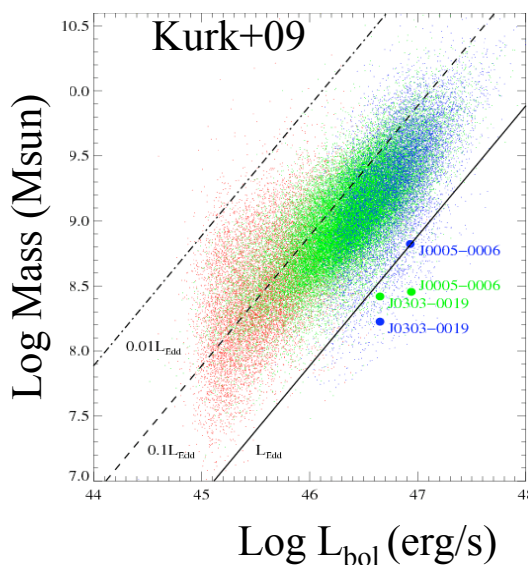

About **40** QSOs at $z > 5.6$, **~15** at $z > 6$, mostly from SDSS which traces the brightest QSOs ($\log L_x \sim 45$, $\log L_{\text{bol}} \sim 46.5$)

SDSS objects at $z \sim 6$ are already “mature”:
high metallicity and large 10^8 - 10^9 Msun BH masses
(Juarez +09, Kurk +09)

Multiple mergers of gas-rich galaxies starting at $z > 14$ and fueling Eddington limited accretion might explain both BH and host galaxy properties of SDSS QSOs at $z > 6$:

OK: metal abundances, BH mass and L/L_{Edd}

?: $M_{\text{BH}}/M_* \sim 0.002$, as in the local Universe, while observations suggest $M_{\text{BH}}/M_* \sim 0.1$

But SDSS QSOs likely NOT representative of whole $z > 6$ pop.

Some key questions on the high- z Universe

How and when the bulk of the first BHs form and grow?

What formed first, BH or galaxy?

What are the scaling relations between BH and host galaxy properties at high- z (but also at all z)?

What is the high- z BH mass function?

How do accretion modes evolve? [radiative efficiency, L/L_{Edd} , SED(α_{ox})]

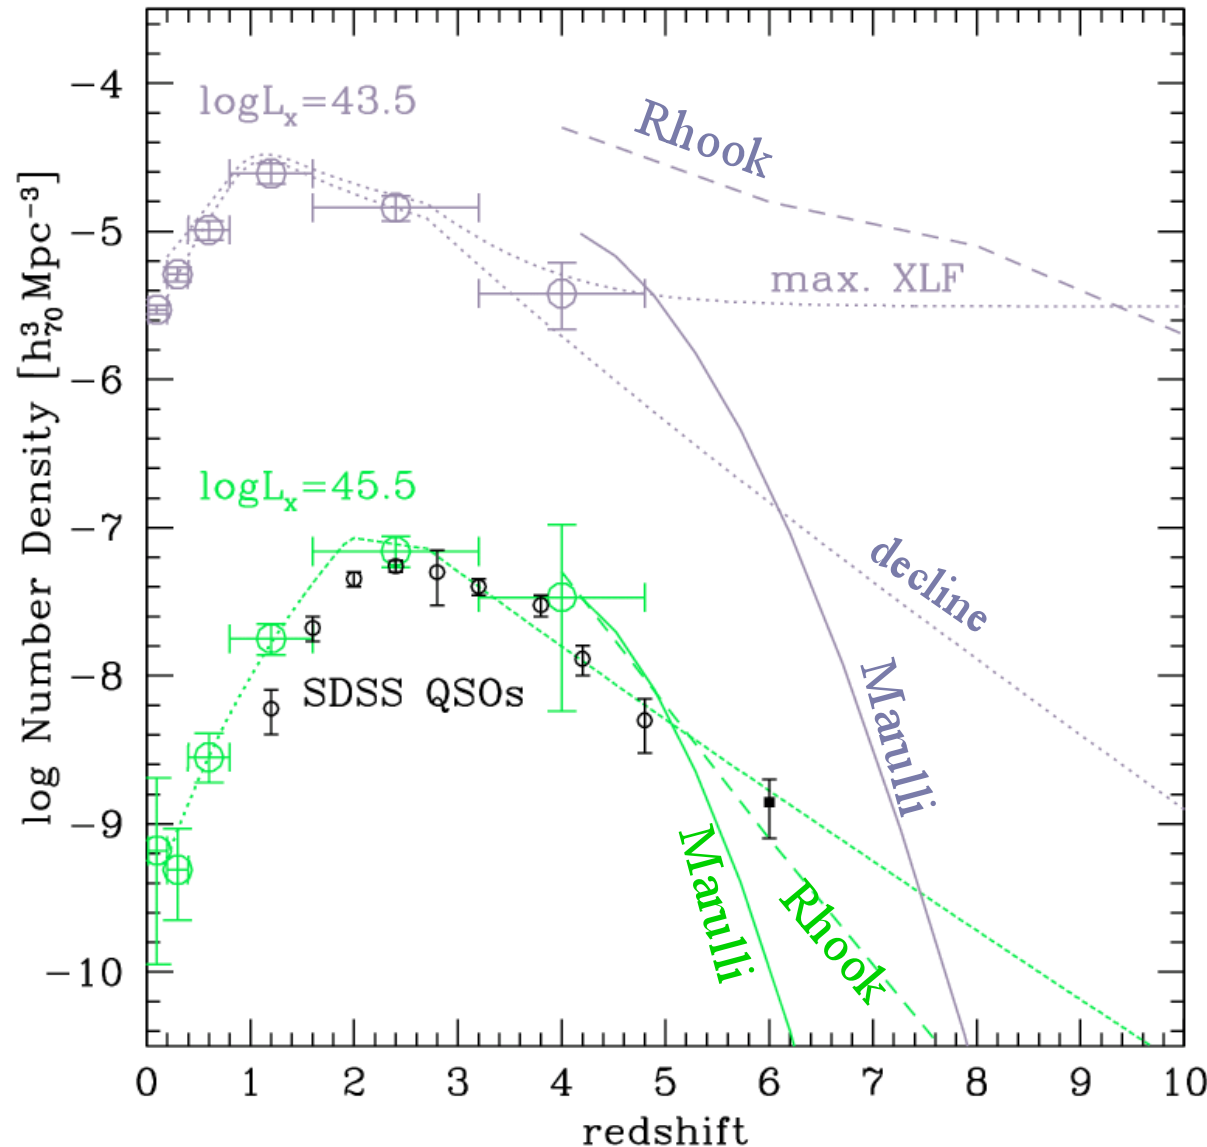

All above issues need object statistics

How many WFXT will see? Extrapolations of known XLF

max. XLF:
XLF that predicts
the maximum
number of high- z
AGN while being in
agreement with
current data.

How many WFXT will see? SAMs of early BH growth

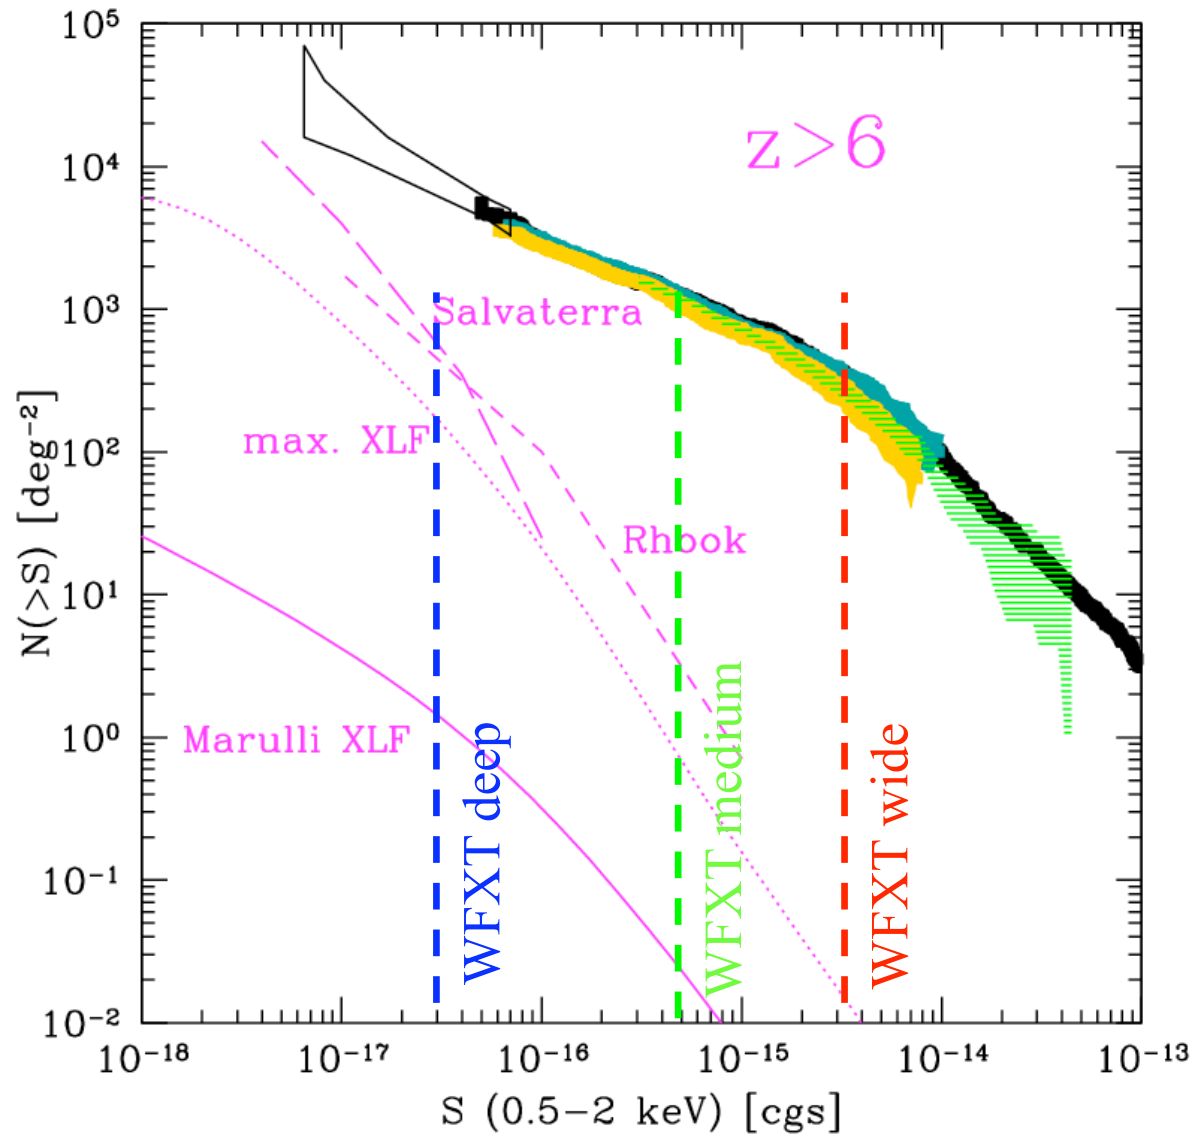

Completely uncharted territory:
predictions for high-z Universe **very** uncertain, even by a few orders of magnitude

Some free parameters of SAMs:

- BH seed mass and location ($N\sigma$ peaks)
- Accretion recipes
- Room for internal processes

AGN at $T_{\text{Universe}} < 1 \text{ Gyr}$

Very wild range of predictions for $z > 6$ AGN:

Observations of significant samples at $z > 6$ would constrain the physics of early BH formation disentangling between several scenarios

How many WFIRST will see?

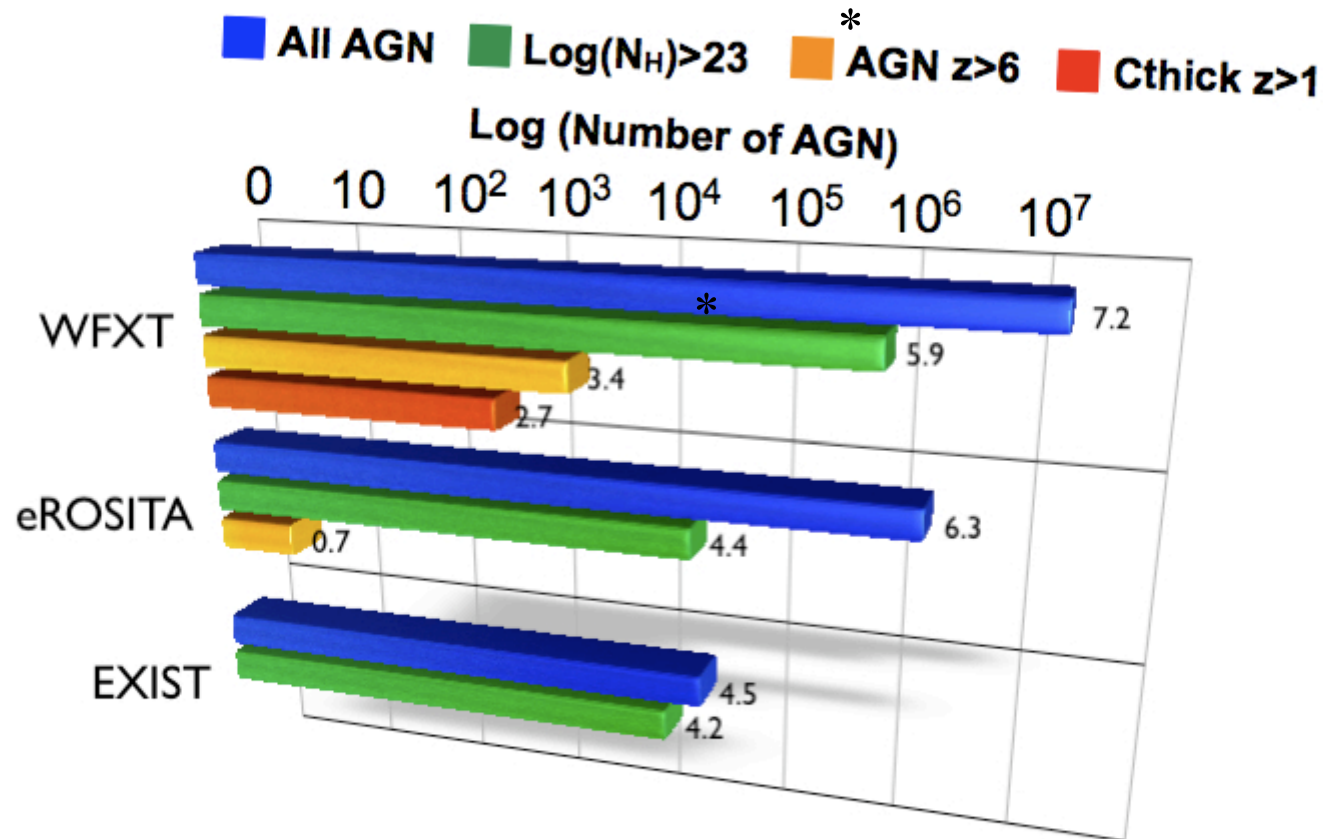

The expected number of AGN

Sample	Wide	Medium	Deep	Total
<i>z>4 decline</i>	<i>30600</i>	<i>38000</i>	<i>6100</i>	<i>74700</i>
z>4 maxlf	31300	54100	43600	1.3e5
z>4 SAM*	55600	84000	34600	1.7e5
<i>z>6 decline</i>	<i>660</i>	<i>1350</i>	<i>310</i>	<i>2320</i>
z>6 maxlf	680	3650	11950	16280
z>6 SAM	30	105	110	245
<i>z>8 decline</i>	<i>22</i>	<i>59</i>	<i>19</i>	<i>100</i>

logNH>23	1.9e5	4.1e5	1.8e5	7.8e5
Total AGN	1.0e7	4.0e6	5.0e5	1.5e7

Statistics large enough to determine the XLF of z>6 AGN

* Semi-analytic model by Marulli+08

Comparison with other missions

WFXT will provide a large sample of high-z objects for statistical studies (BH formation, evolution)

science case
unique to WFXT

*assuming a decline

AGN at $T_{\text{Universe}} < 0.65 \text{ Gyr}$

23 April 2009: GRB discovered at redshift $z=8.26$; Y-band dropout

Tanvir+09, Salvaterra+09

~ 100 AGN at $z > 8$ expected in WFXT surveys:

22 wide

59 medium

19 deep

(based on the “decline” scenario, the relative fractions among WFXT surveys change with the assumed evolution)

Evolution of the obscuration

Current XLFs contain $< \sim 2000$ AGN
(Hasinger+08, Aird+09, Yencho+09)

N_H mostly comes from HR or low
quality spectra. What is the XLF and
evolution of obscured AGN?

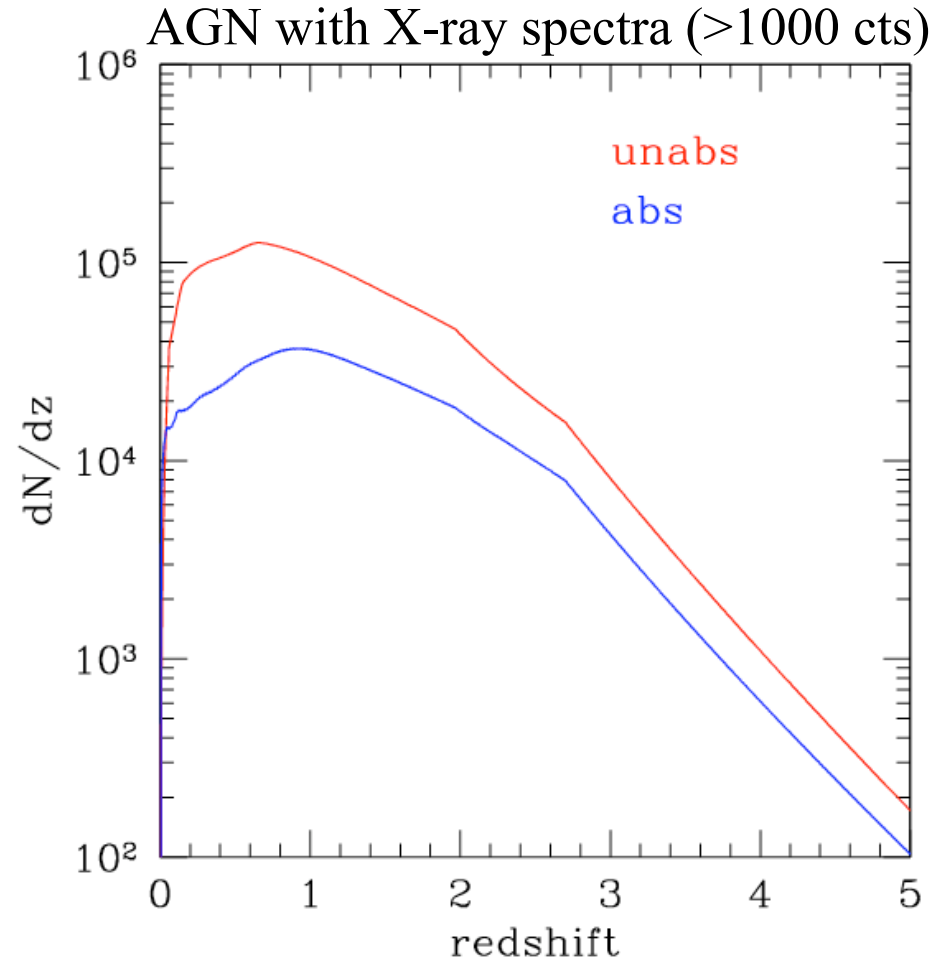

With WFXT:

300,000 AGN with X-ray spectra
at $z=[0-5]$

200,000 unabsorbed

100,000 absorbed

→ evolution of obscuration measured
(provided spectro- z or photo- z are
available)

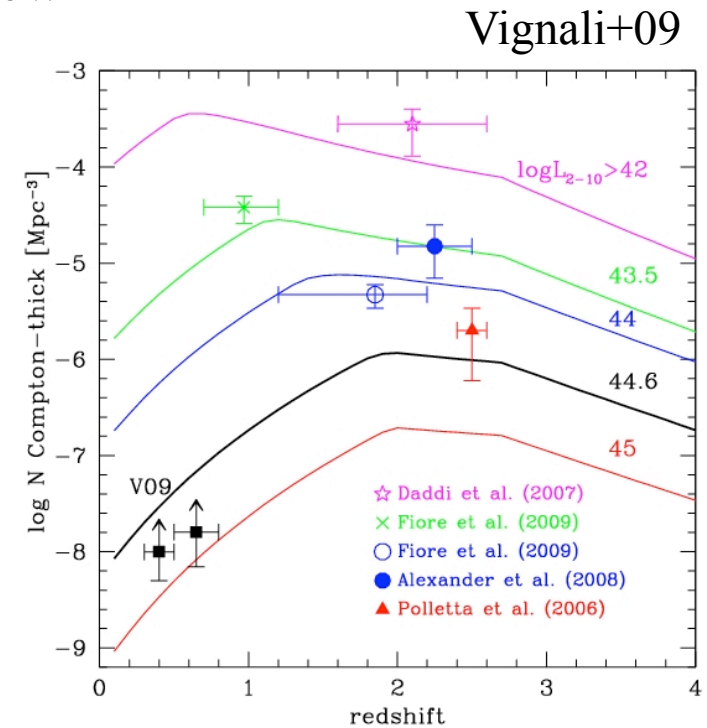

The most obscured objects: Compton thick AGNs

About 50 *bona fide* C-thick AGN known, mostly at $z < 0.1$. Recent attempts to determine the size of the C-thick population rely on X-ray stacking of IR selected objects or X-ray/[OIII] ratio, **i.e. no direct measurement**

C-thick AGN at $z \sim 1$ invoked to explain the 30 keV XRB, however their XLF and evolution completely unknown

Plotted errorbars are statistics, but in fact systematics dominate the uncertainties

Two examples of distant Compton-thick AGN

CDFS-153, $z=1.5$

XMM 1.8 Msec spectra

CDFS-202, $z=3.7$

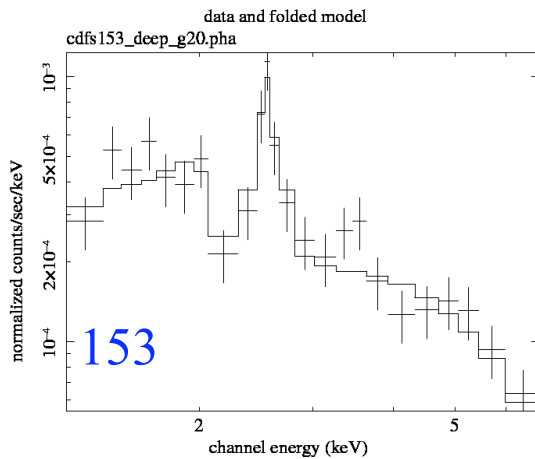

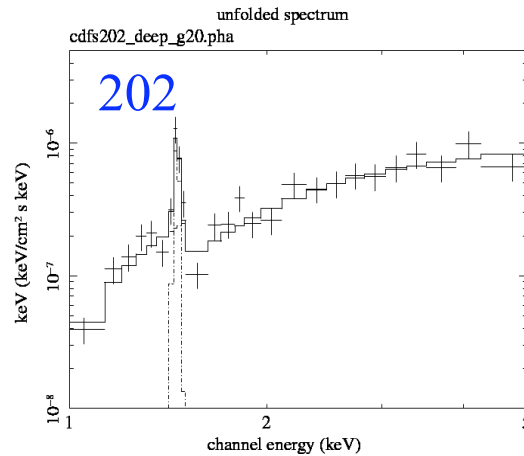

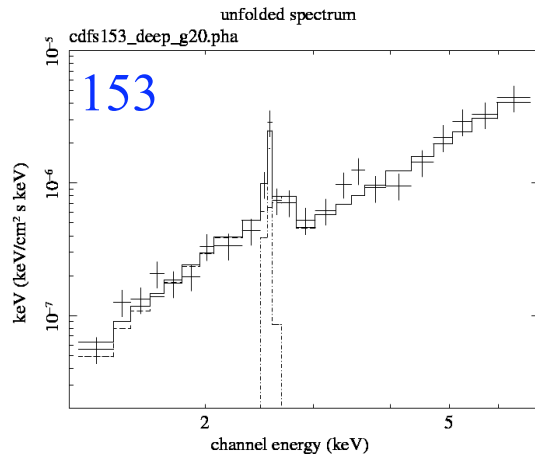

~ 650 net cts

~ 320 net cts

CDFS-153 and CDFS-202 in the WFXT Deep (100deg², 400ks) survey

~500 cts 0.5-7 keV

About 500 objects like these expected at $z > 1$, enough for population studies ← **UNIQUE**

Here C-thick nature established source by source from the X-ray spectrum. In principle no need for identification (z from the Fe line)

$z >$	Number
1	500
2	270
3	60
4	12

No bkg in the spectral simulations, but few (~ 10-20) bkg counts expected at $E > 1$ keV

Final remarks

- ~15 millions AGN detected by WFXT; 300,000 with more than 1000 net cts, i.e. accurate N_H → evolution of obscured AGN, e.g. abs/unabs vs z
- WFXT will break through the high-z Universe: >2000 AGN at $z>6$ → AGN population studies at $z>6$ * UNIQUE *
- ~500 *bona fide* C-thick AGN at $z>1$ in the WFXT deep survey → Evolution of high-z C-thick population * UNIQUE *
