

The structure of AGNs from X-ray Absorption variability

Guido Risaliti (Arcetri & CfA)

Ubiquitous Variability of N_H in Seyfert Galaxies

N_H variable in 23/25 sources

Timescales from months to years

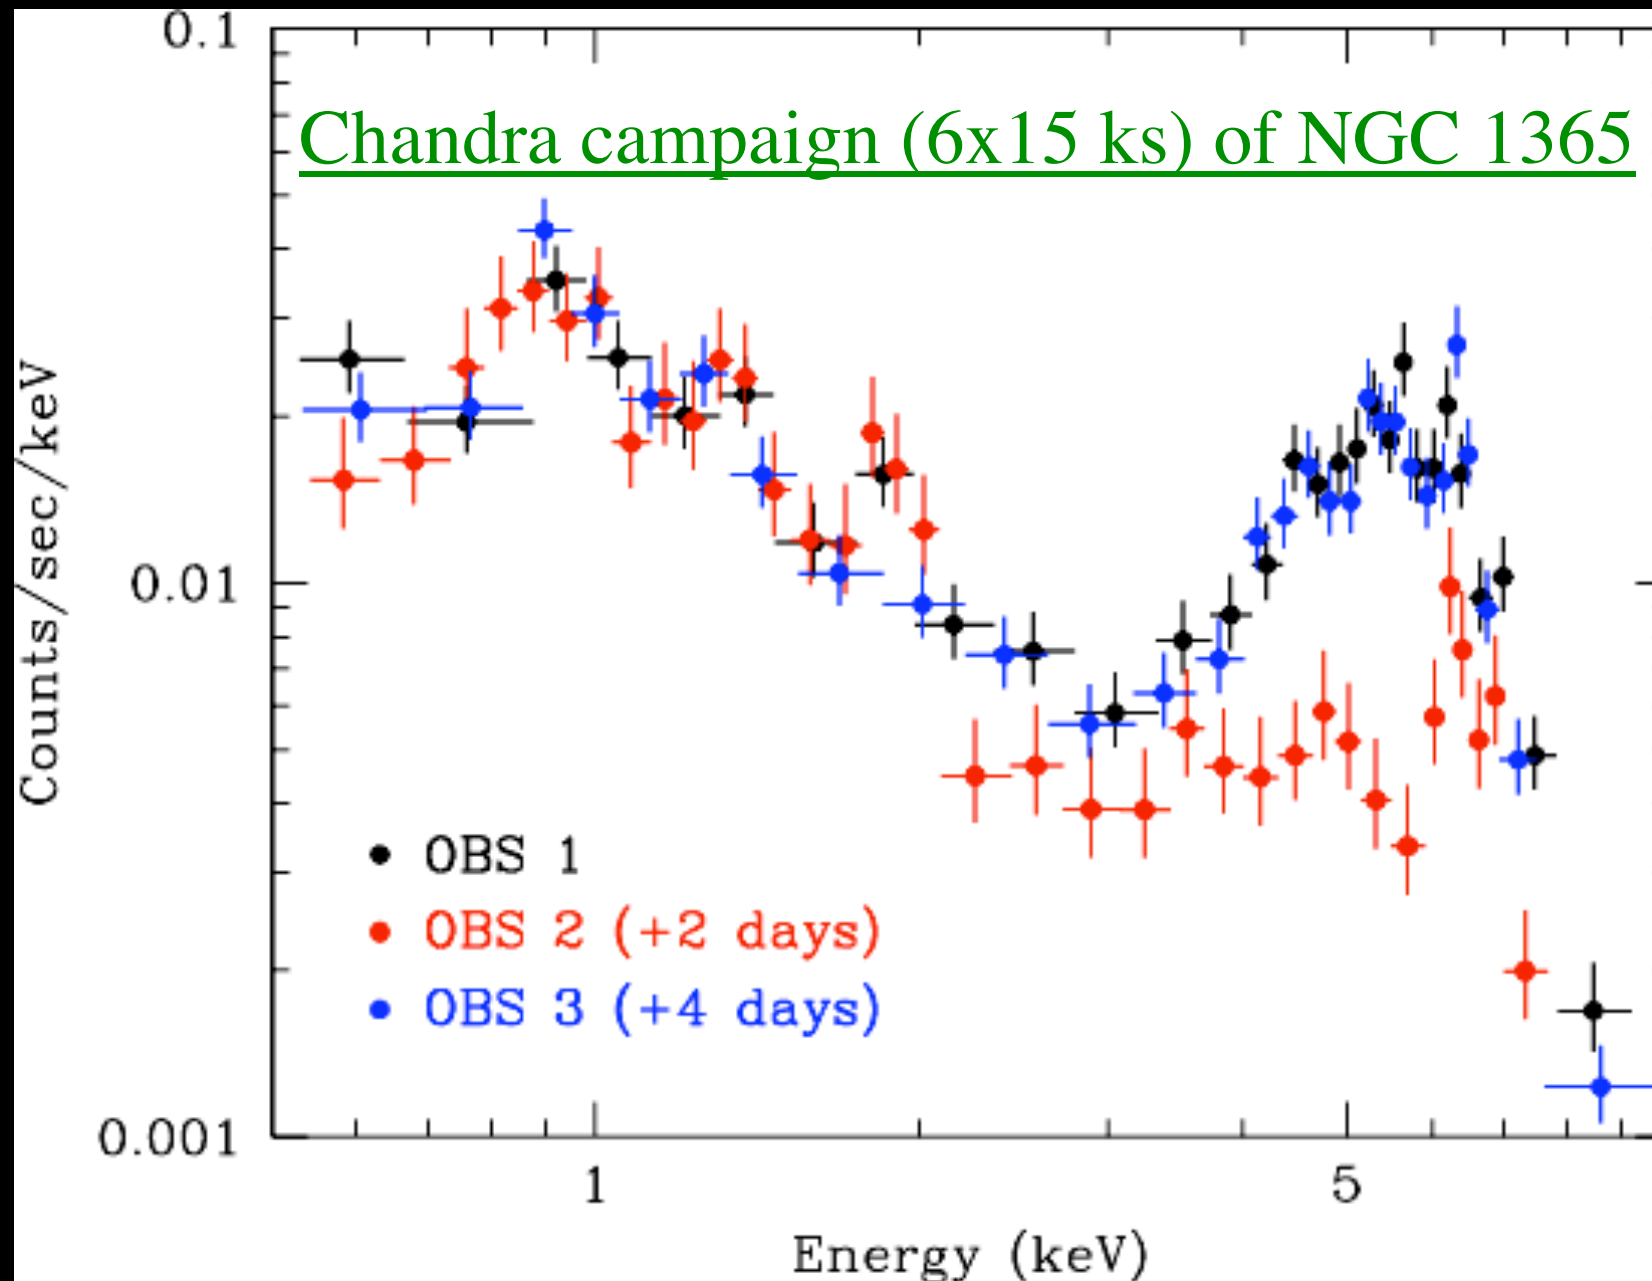

Clumpy absorber
Sub-parsec distance

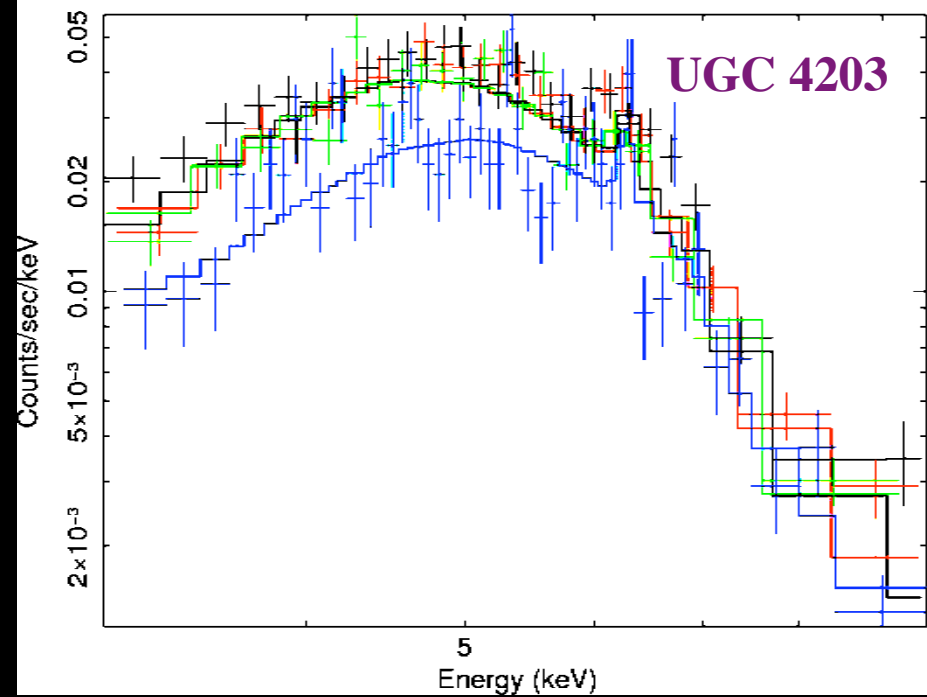

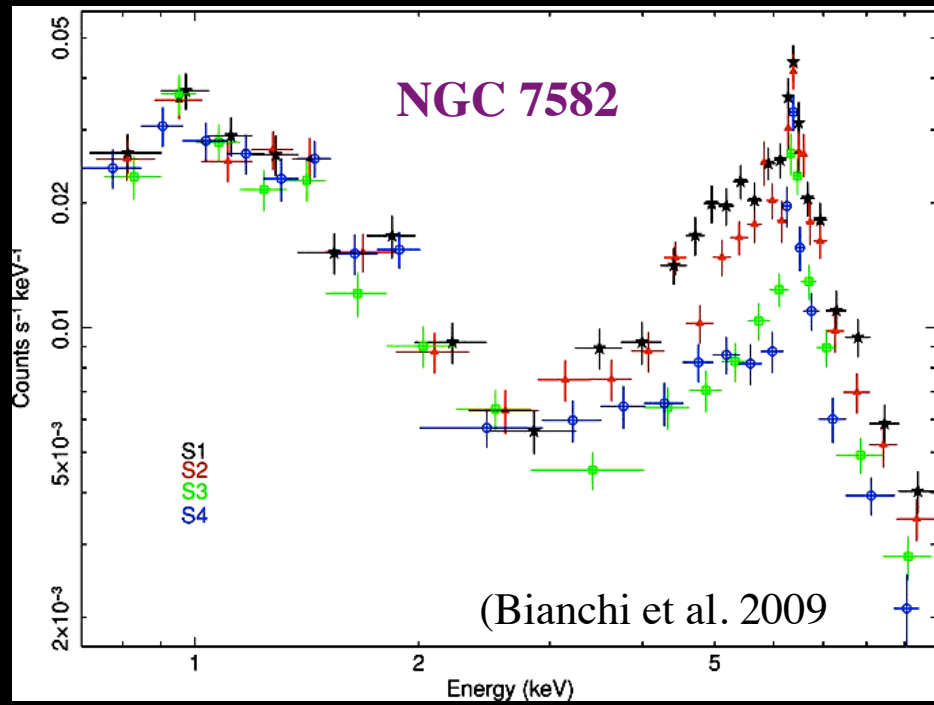

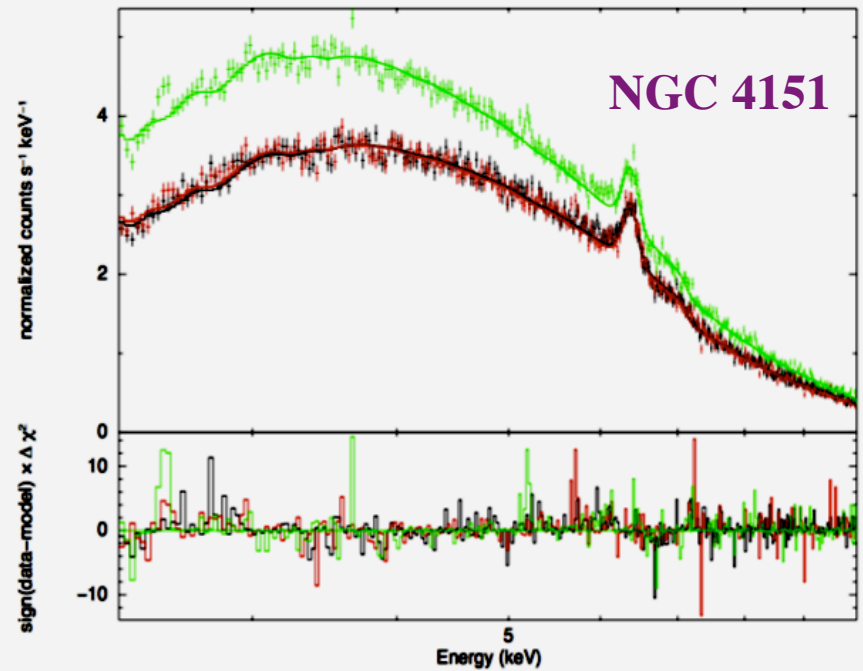

Next step: Search for column density variations in hours -- days

Two methods:

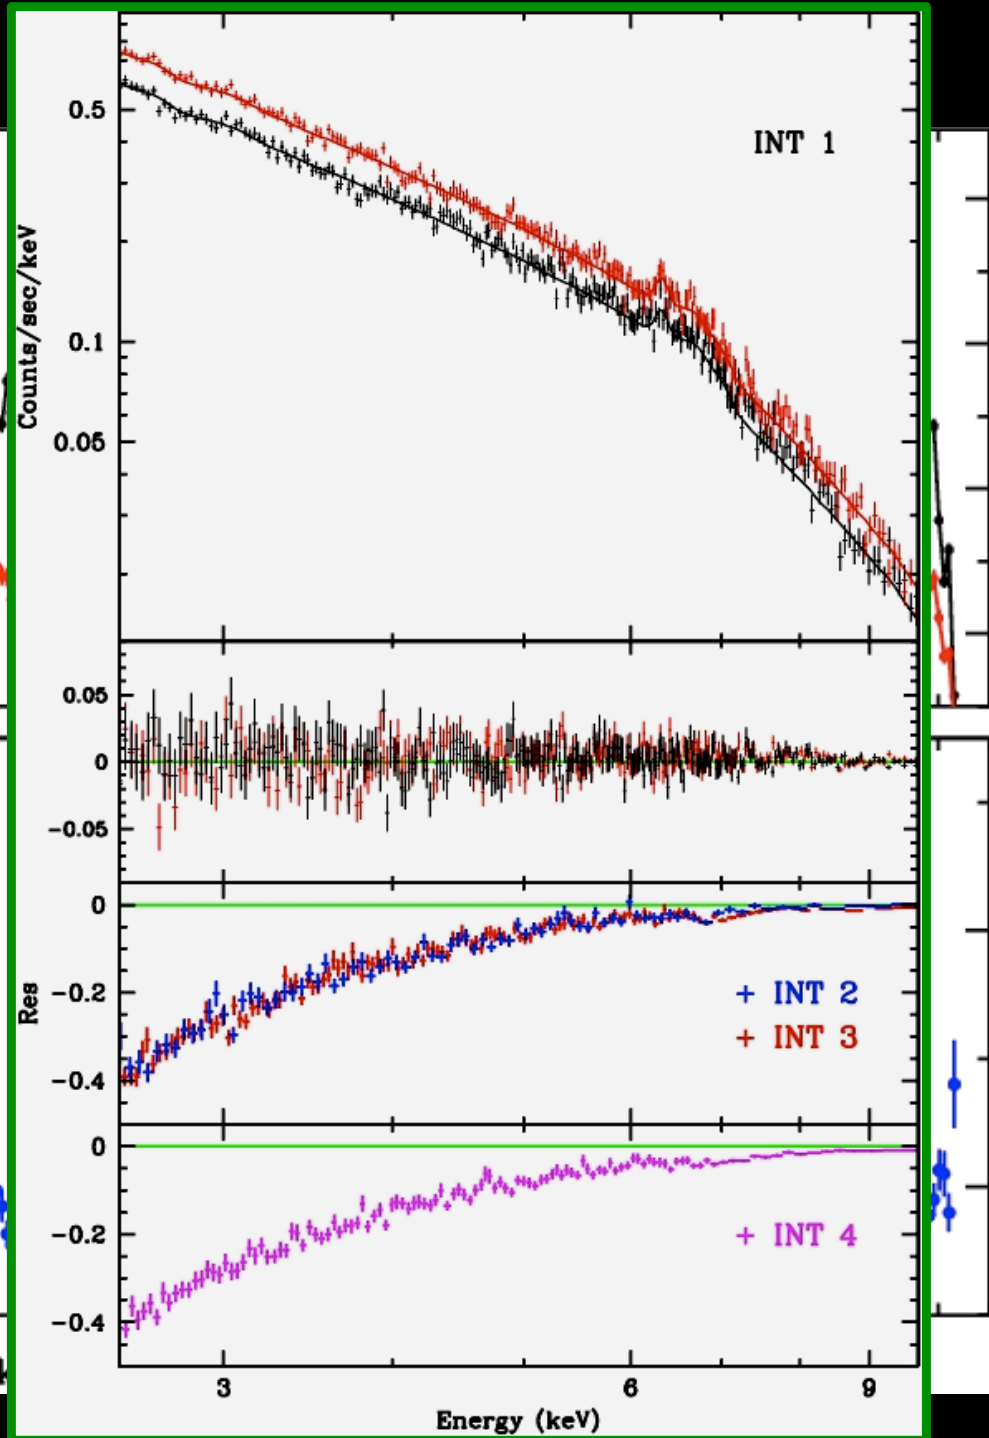

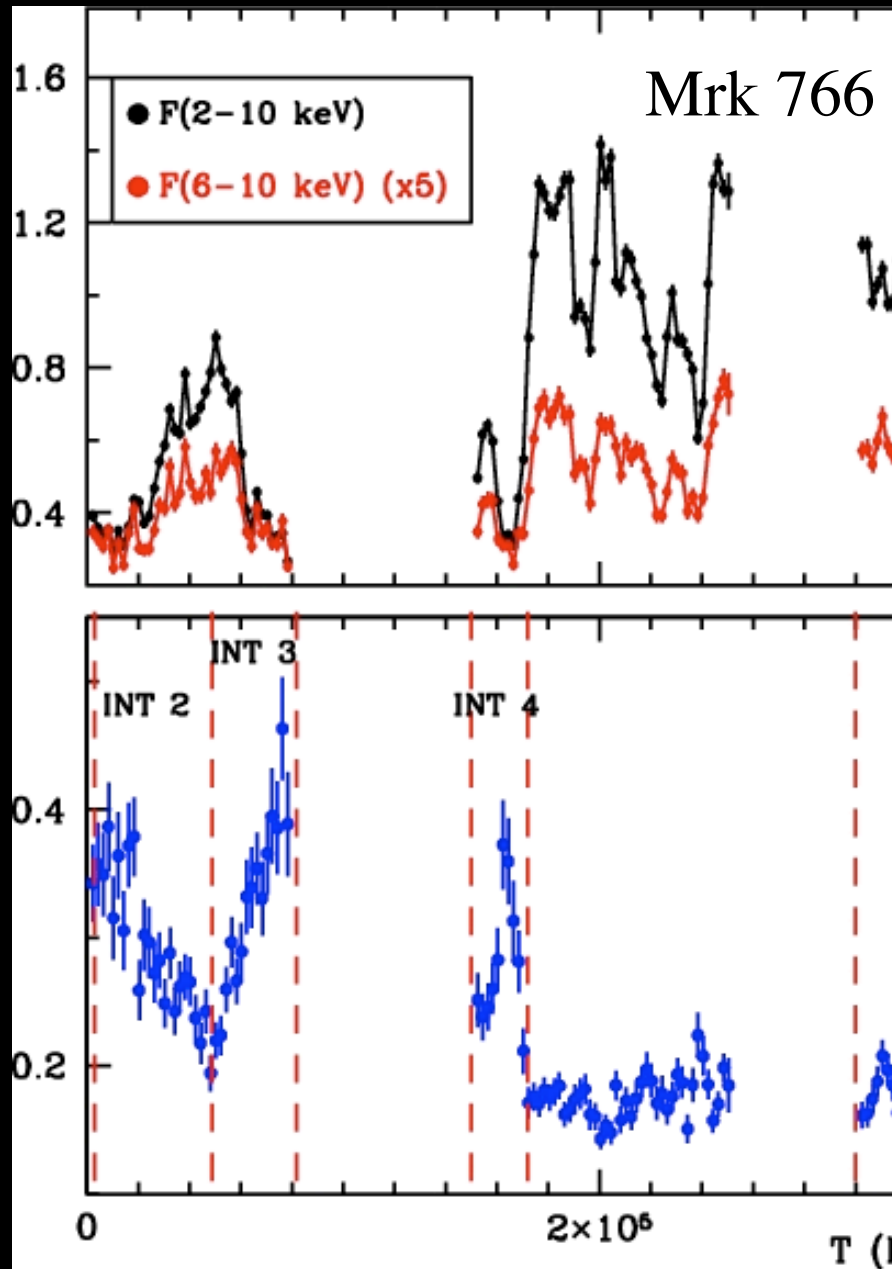

- 1. Campaigns of snapshot observations within ~a few days**
- 2. Analysis of HR light curves in long observations**

1) Repeated snapshot observations

2) Single long observations

NGC 4388

NGC 4151

Puccetti et al. 2007)

General results:

Eclipses of the X-ray source are COMMON in nearby AGN

$$\Delta N_{\text{H}} \sim 10^{23} - 10^{24} \text{ cm}^{-2}$$

$$V > 10^3 \text{ km/s}$$

$$D \sim 10^{13} \text{ cm}$$

$$n \sim 10^{10} - 10^{11} \text{ cm}^{-3}$$

X-ray absorber = BLR clouds

NGC 1365 in high state: Suzaku observation

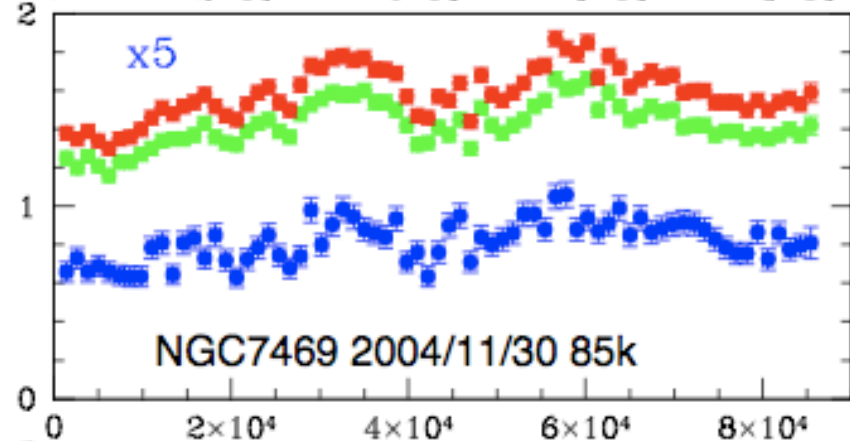

Shape, size and dimensions of BLR clouds

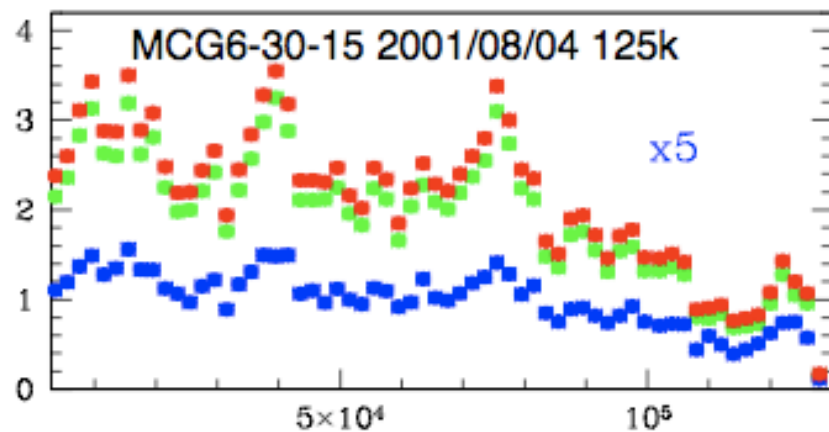

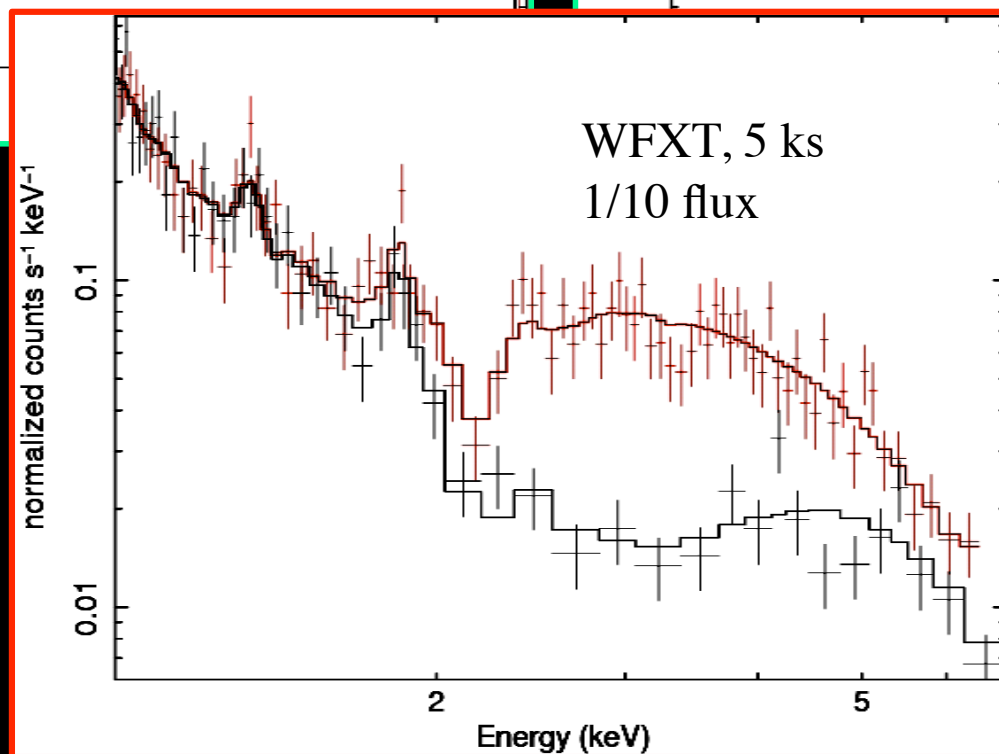

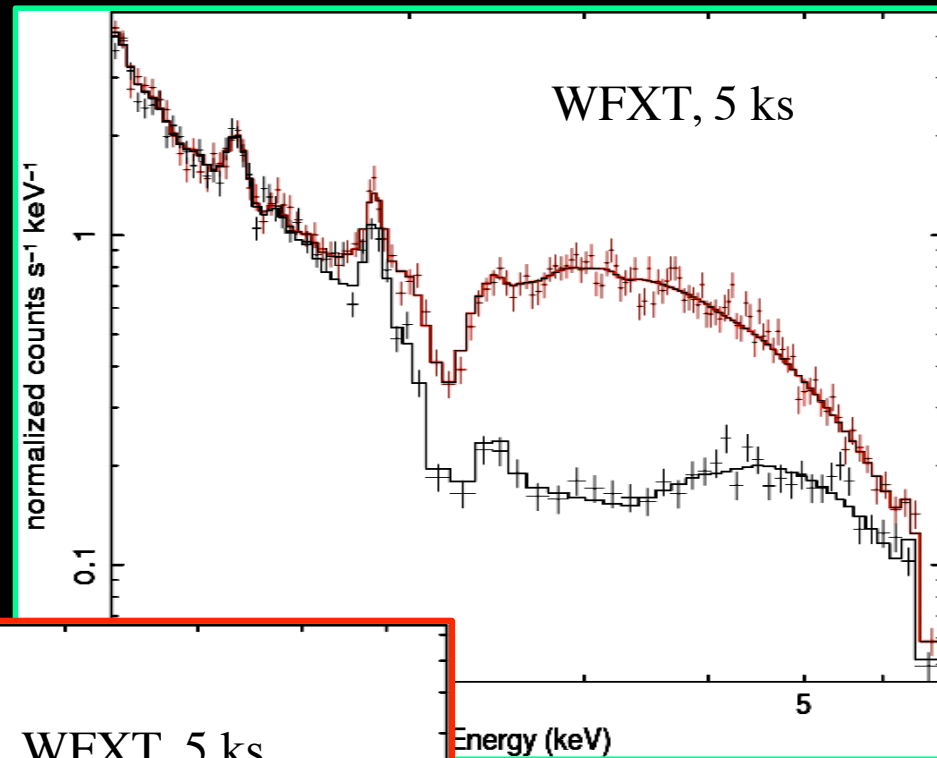

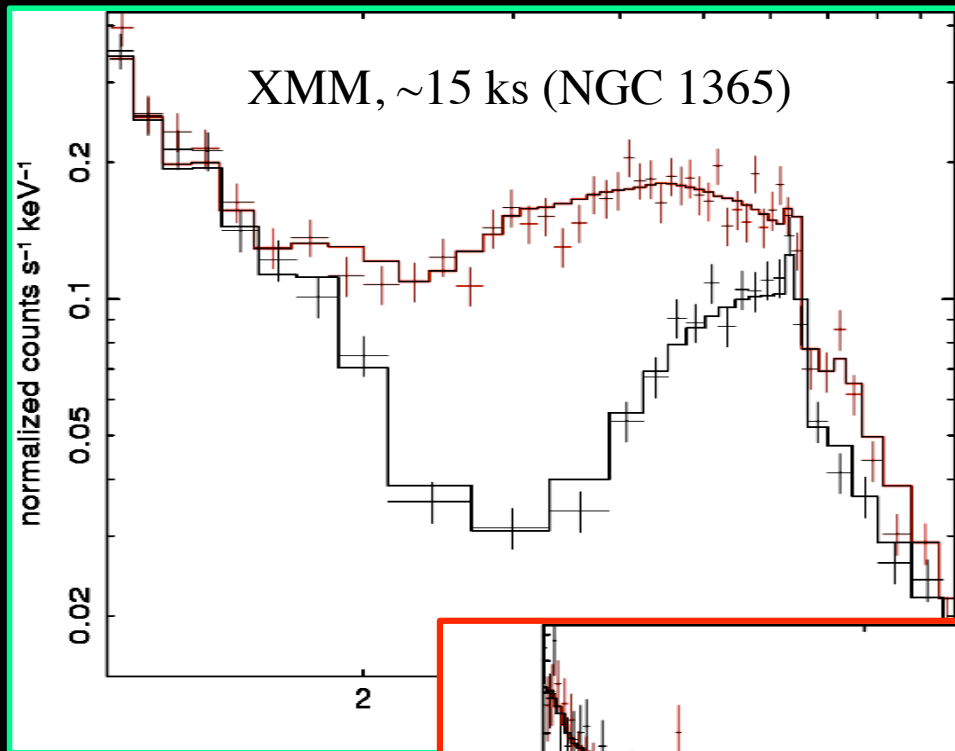

LIMITATIONS:

- Fluxes: $F(2-10)_{\text{INTR}} > 10^{-11} \text{ erg cm}^{-2} \text{ s}^{-1}$
- Time intervals ($T > 15 \text{ ks}$)
- Non-homogeneous analysis

→ Analysis possible only for the most extreme cases in ~ 15 sources
+ ~ 20 type 1s

WFXT deep survey:

- Statistical analysis of HR variations for hundreds of sources
→ evaluation of the relevance of variable absorption in different classes of AGN
- Spectral analysis of N_{H} variations (analogous to that performed on bright sources with XMM/Suzaku) for several tens – a few hundred sources → determination of average physical parameters (size, shape, density, distance) of BLR/X-ray obscuring clouds
- Time-resolved spectroscopy on time scales of a few 100 sec for very bright sources → complete characterization of the BLR/X-ray absorbing clouds
