

# CMB studies with Planck

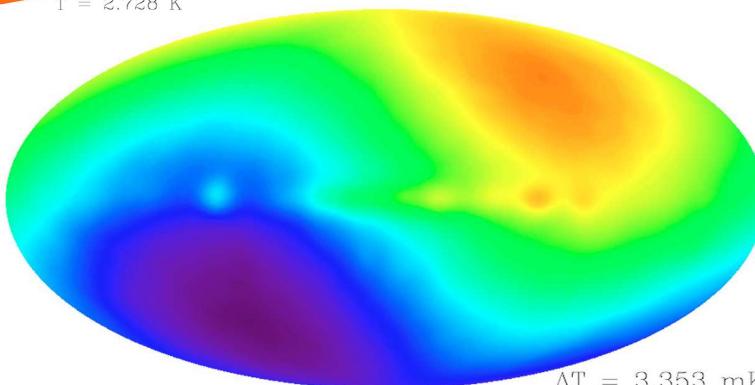

Antony Lewis  
Institute of Astronomy &  
Kavli Institute for Cosmology, Cambridge  
<http://cosmologist.info/>

Thanks to Anthony Challinor & Anthony Lasenby for a few slides

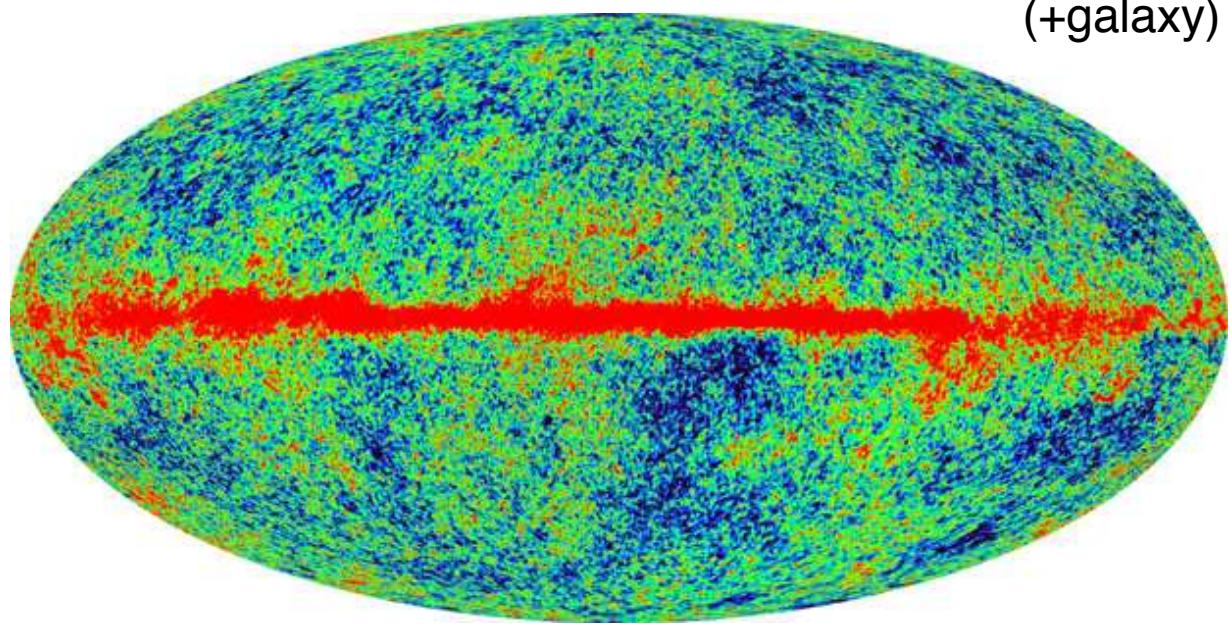

(almost) uniform 2.726K blackbody

Dipole (local motion)

$\Delta T = 3.353 \text{ mK}$

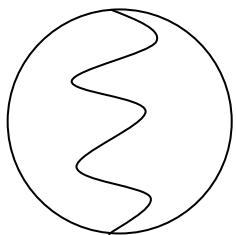

$O(10^{-5})$  perturbations  
(+galaxy)

Observations:  
the microwave  
sky today

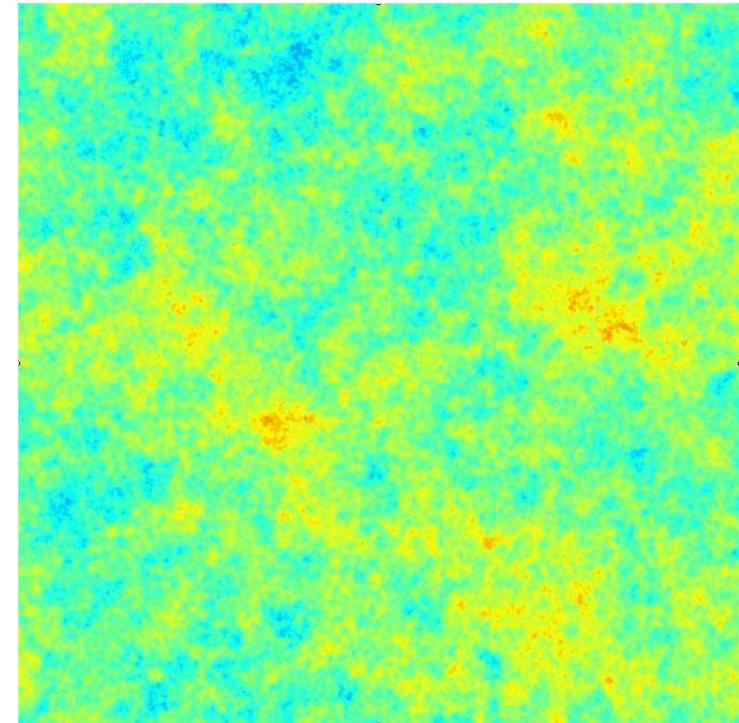

Source: NASA/WMAP Science Team

# Where do the perturbations come from?

**Quantum Mechanics**  
“waves in a box”

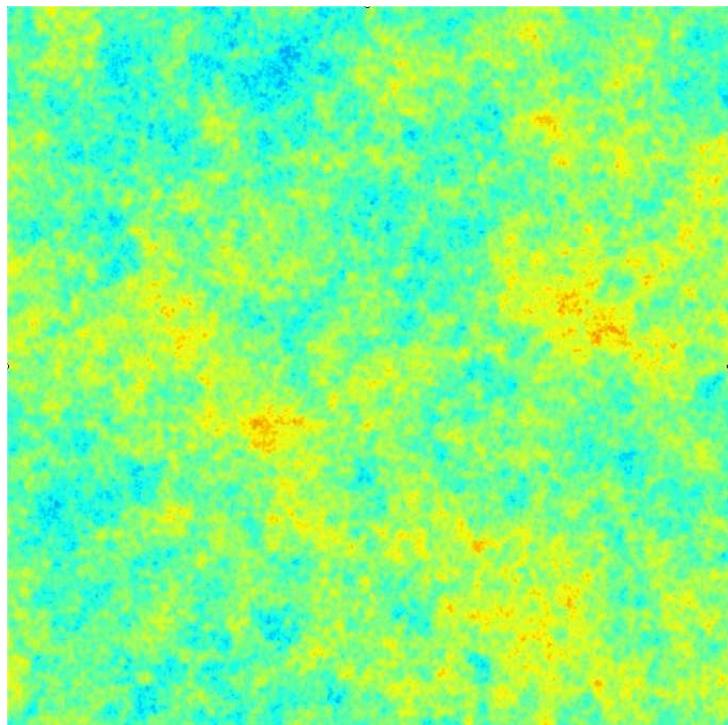

**Inflation**  
make  $>10^{30}$  times bigger

**After inflation**  
Huge size, amplitude  $\sim 10^{-5}$

## CMB temperature

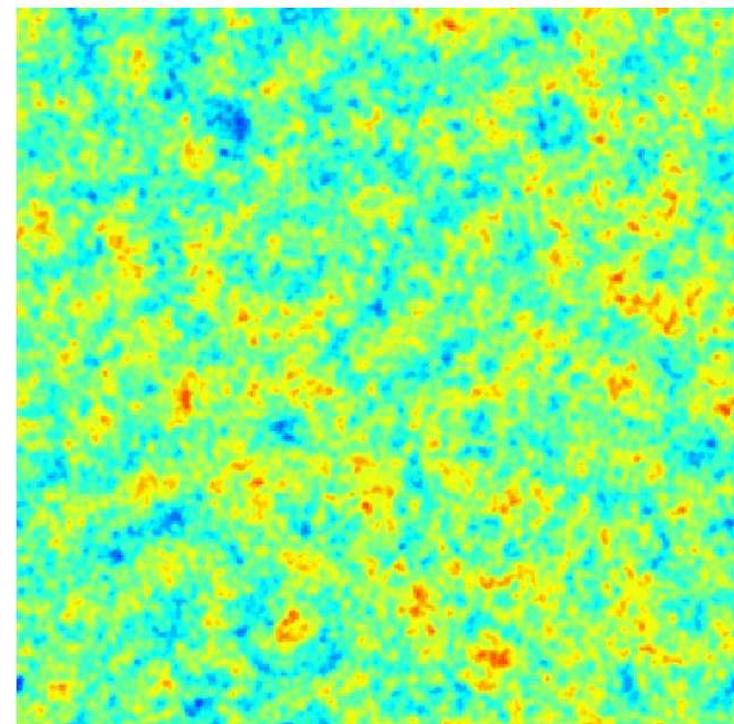

End of inflation

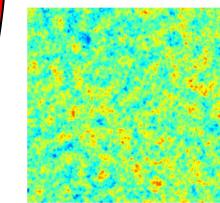

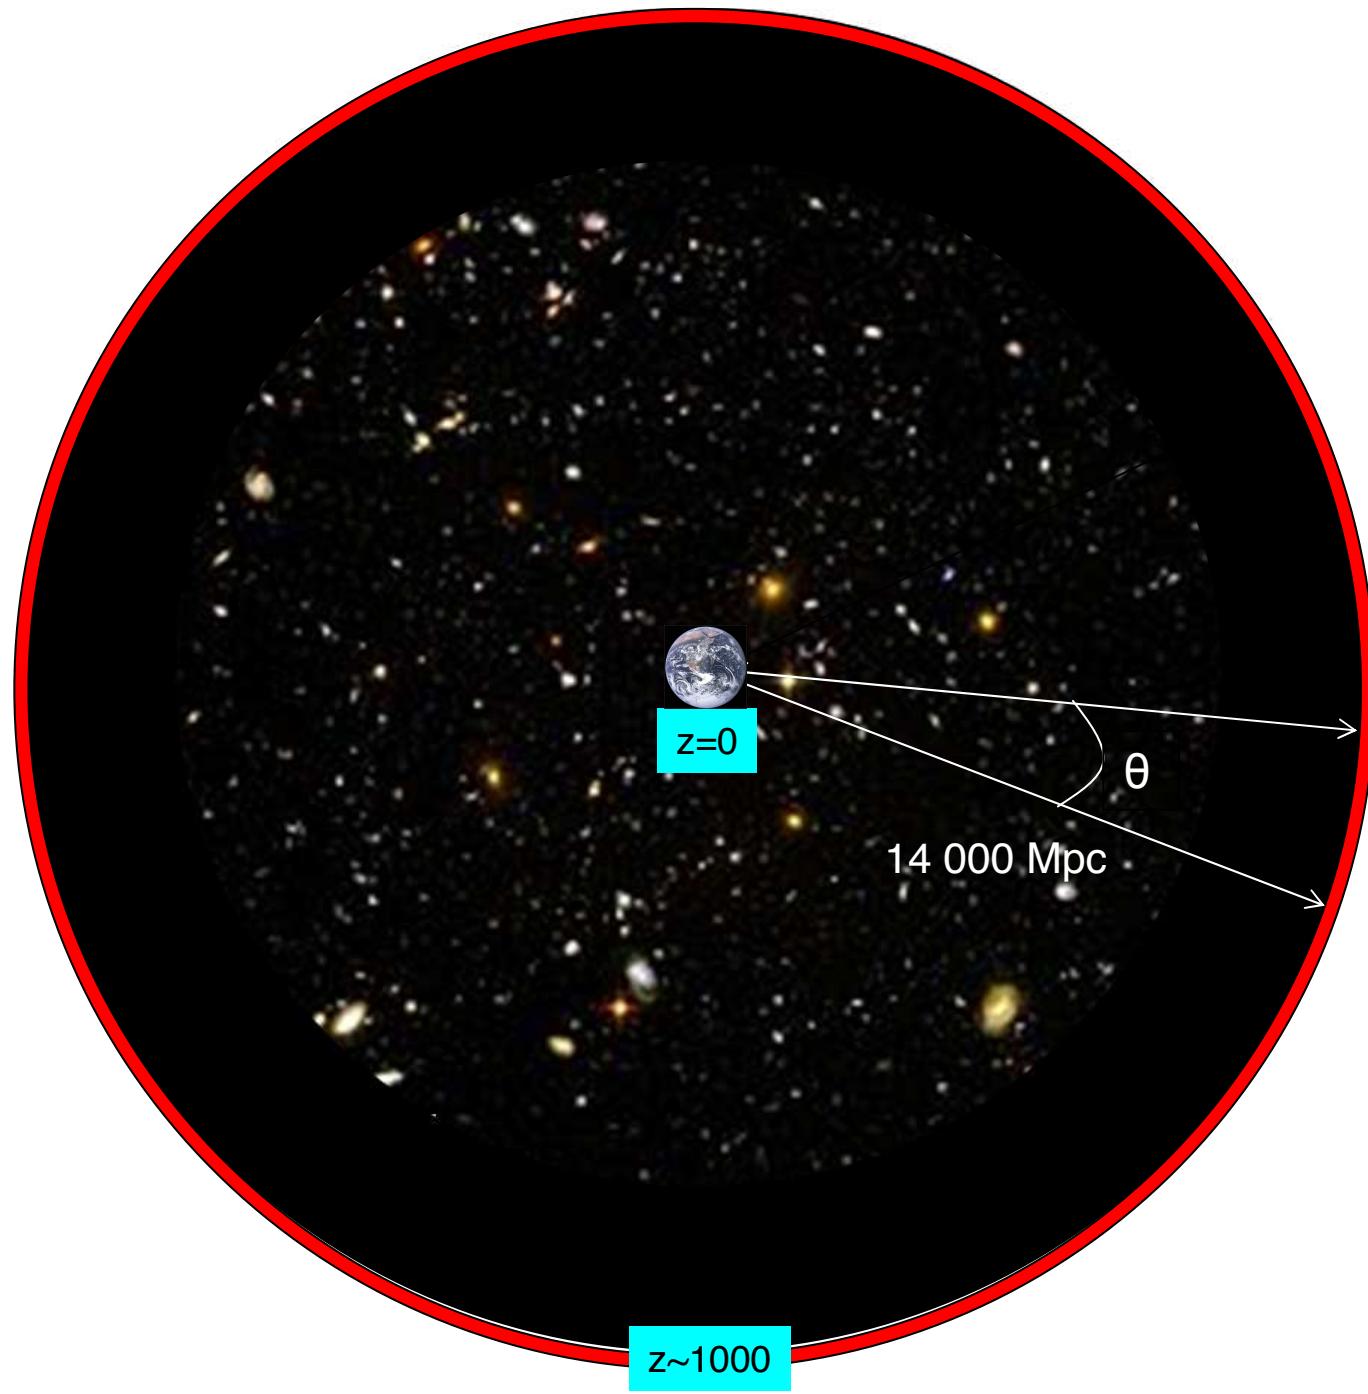

gravity+  
pressure+  
diffusion

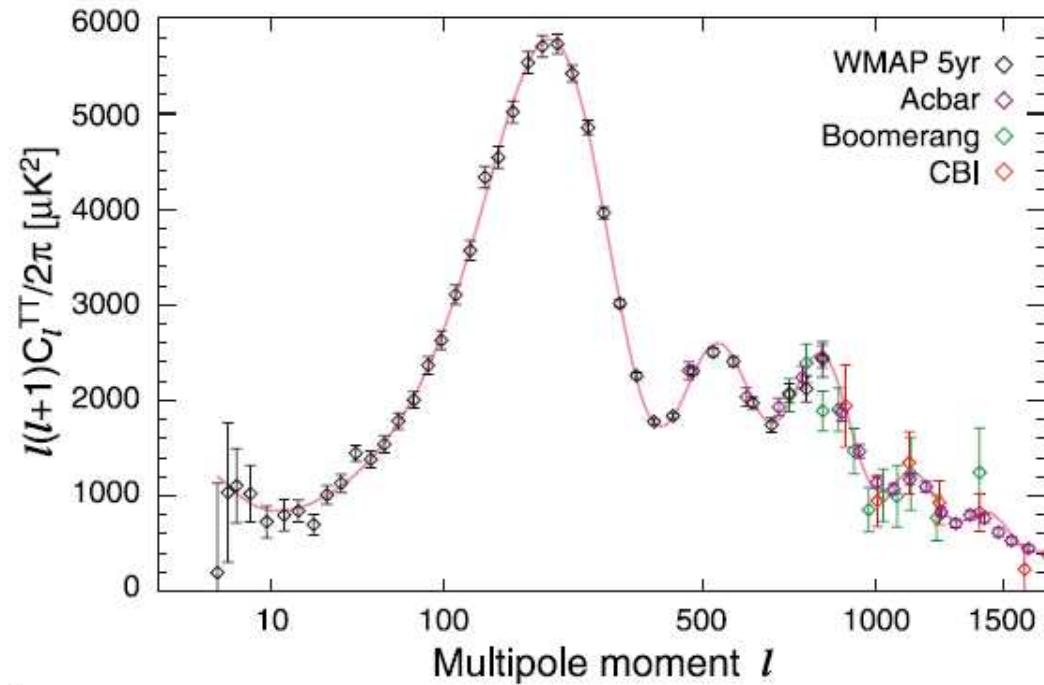

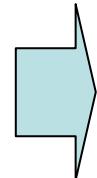

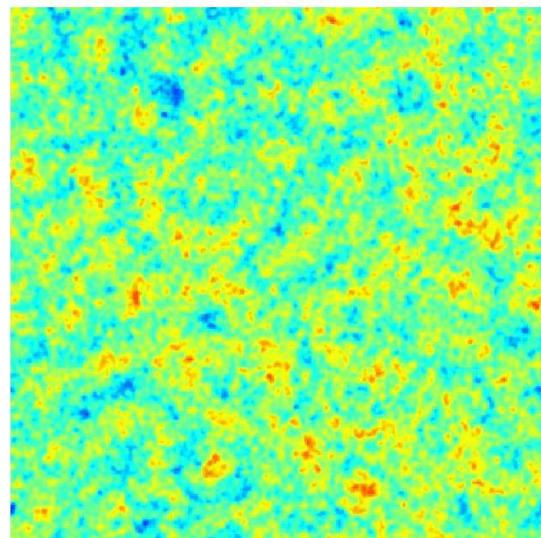

Last scattering surface

# Observed CMB temperature power spectrum

Primordial perturbations + known physics with unknown parameters

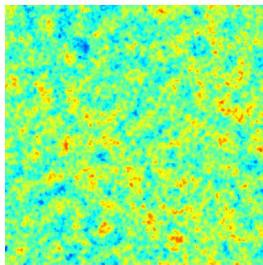

Nolta et al.

Observations

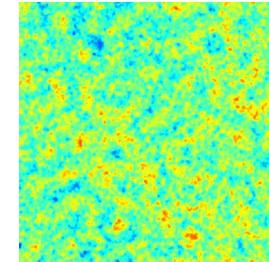

Constrain theory of early universe  
+ evolution parameters and geometry

e.g. Geometry: curvature

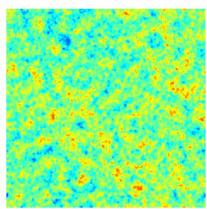

flat

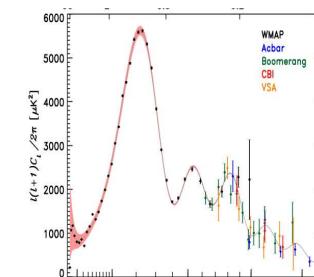

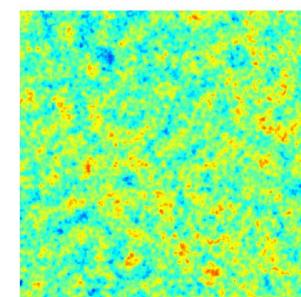

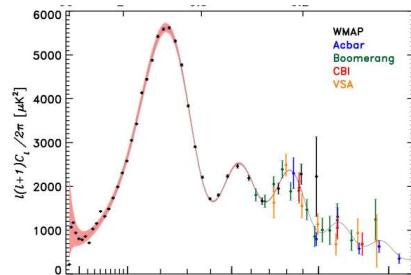

$\theta$

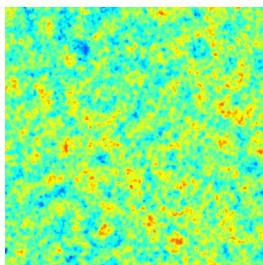

closed

We see:

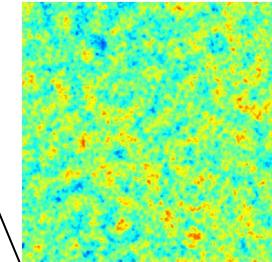

or is it just closer??

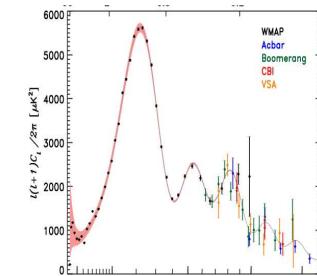

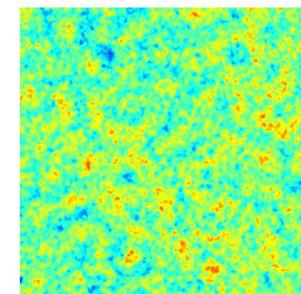

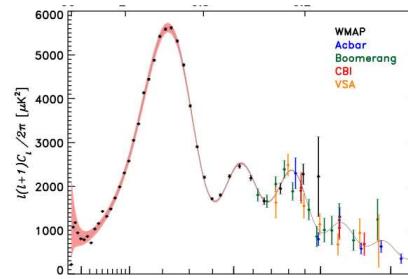

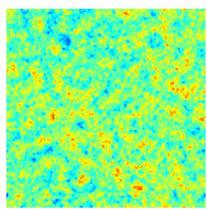

flat

$\theta$

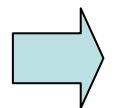

flat

$\theta$

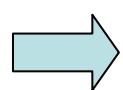

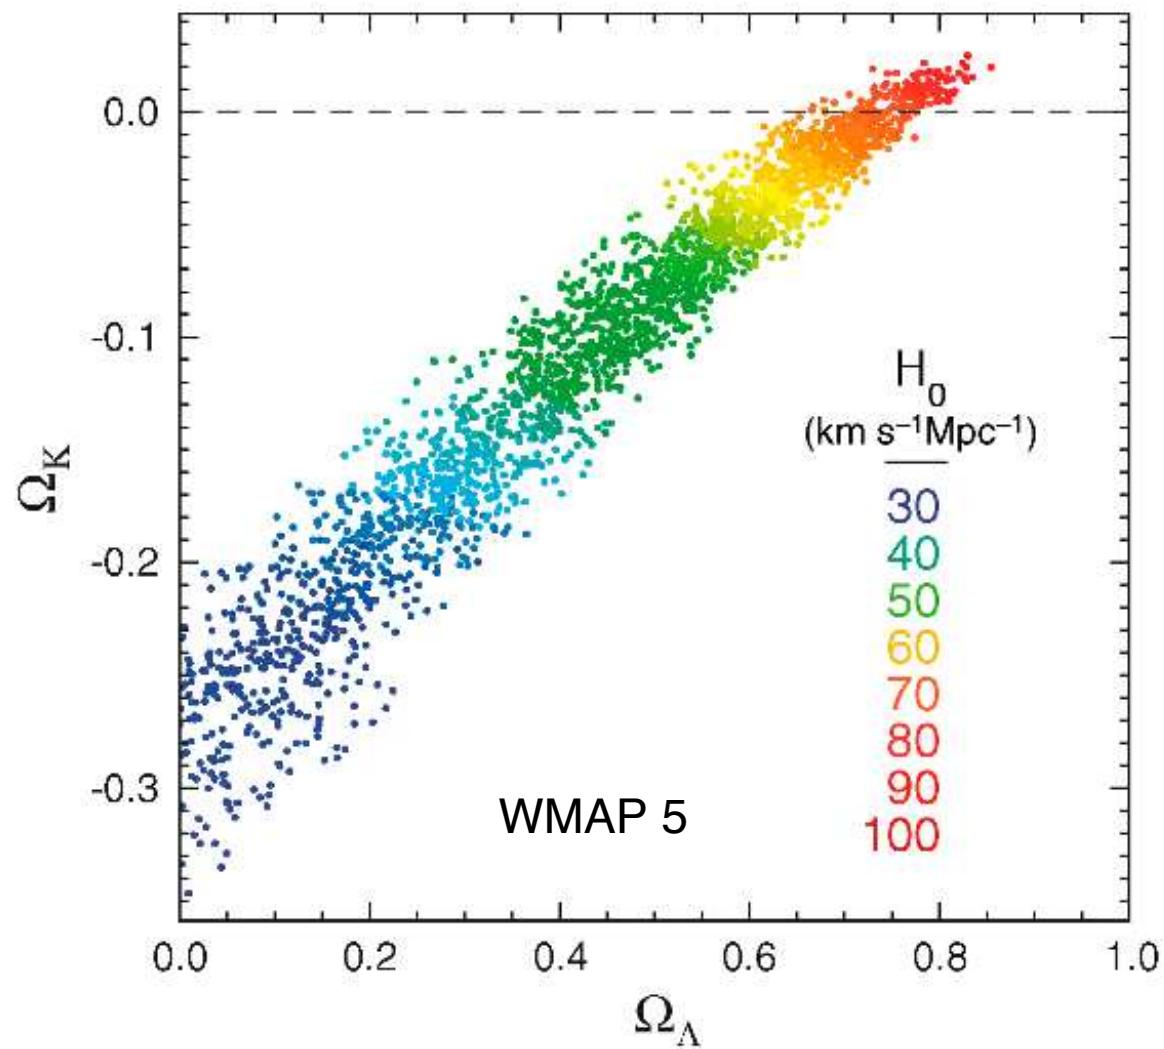

We see:

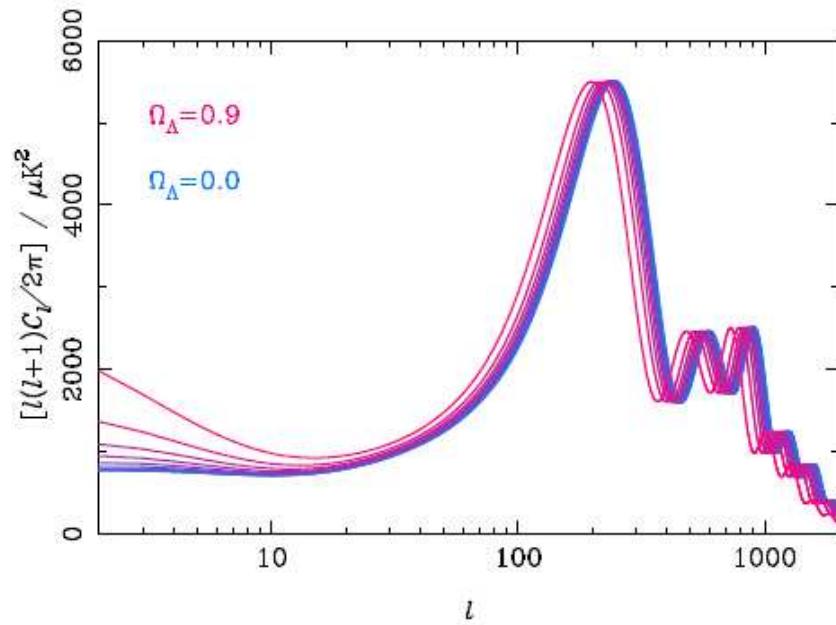

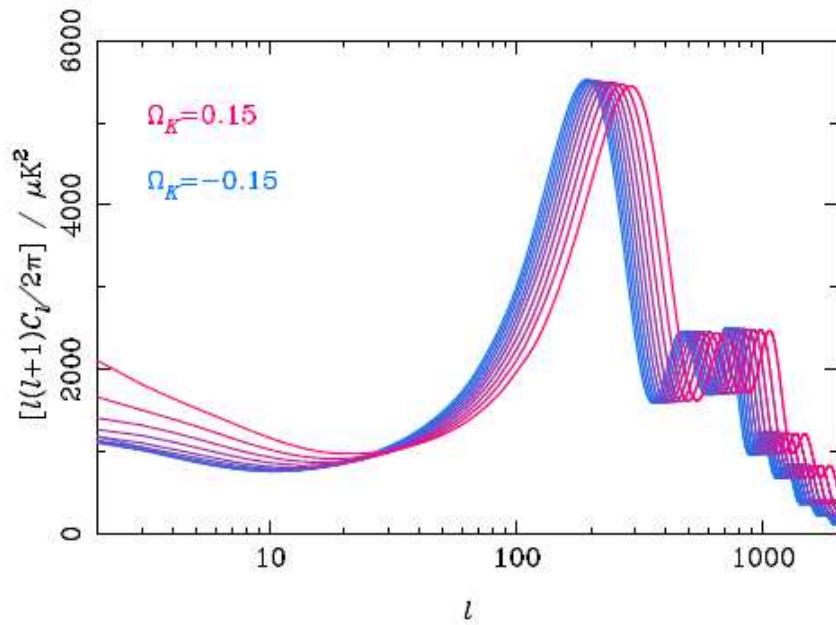

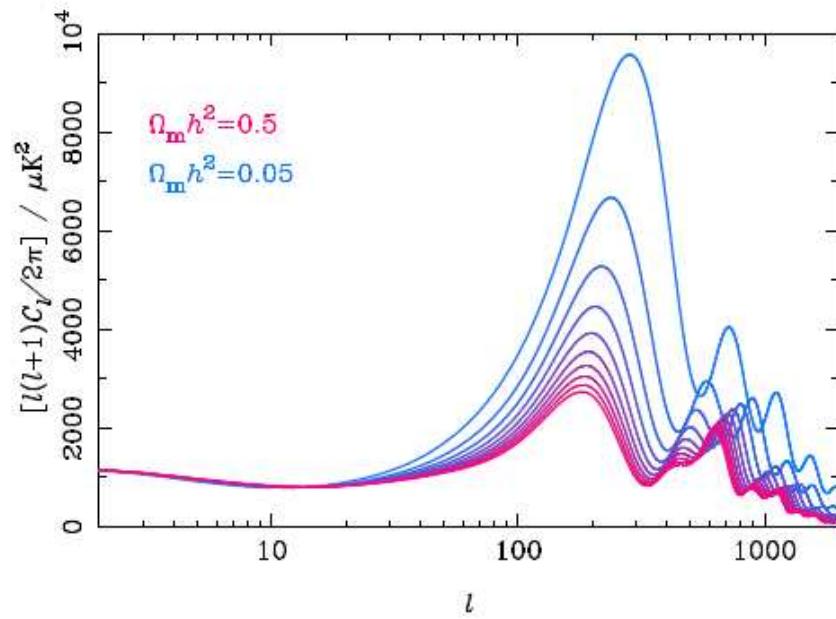

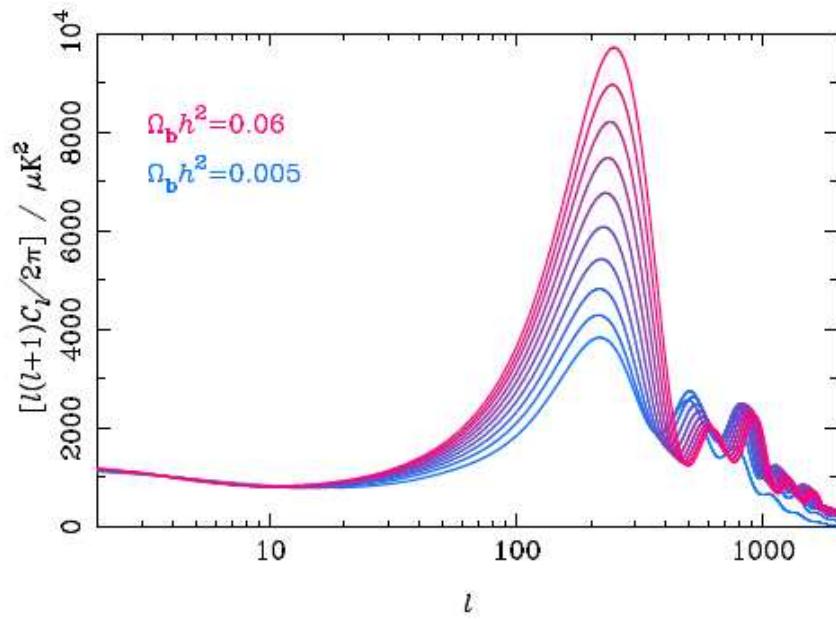

Degeneracies between parameters

Dunkley et al. 2009

Use other data to break  
remaining degeneracies

Credit: Anthony Challinor

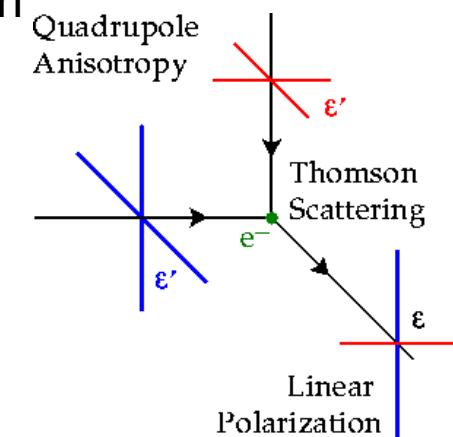

# Polarization: Stokes' Parameters

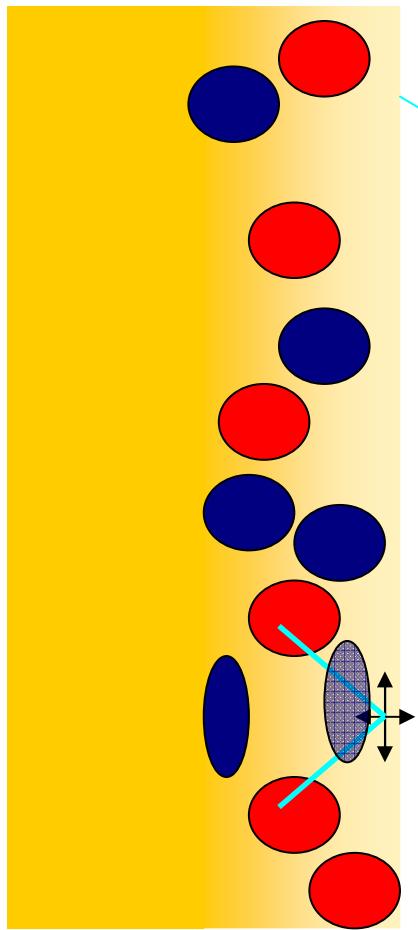

$Q \rightarrow -Q, U \rightarrow -U$  under 90 degree rotation

$Q \rightarrow U, U \rightarrow -Q$  under 45 degree rotation

Generated by Thomson scattering of anisotropic unpolarized light

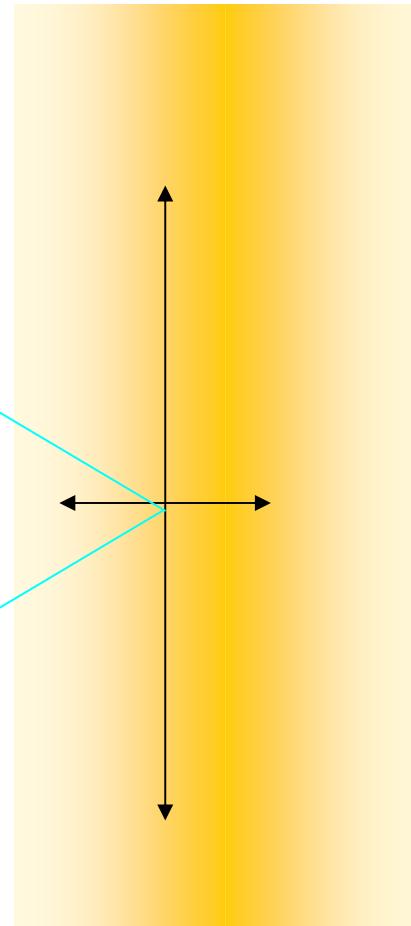

$$n_e \sim x_e (1+z)^3 n_0$$

Local quadrupole at end  
of recombination

Scale of acoustic peaks

Large-scale quadrupole scatters  
at reionization

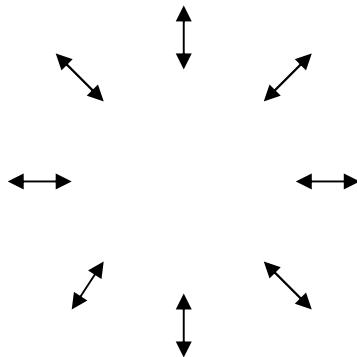

Large-scale  
(coherent over horizon scale at reionization)

# CMB polarization: E and B modes

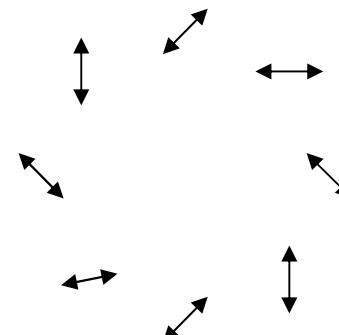

“gradient” modes  
E polarization

e.g.

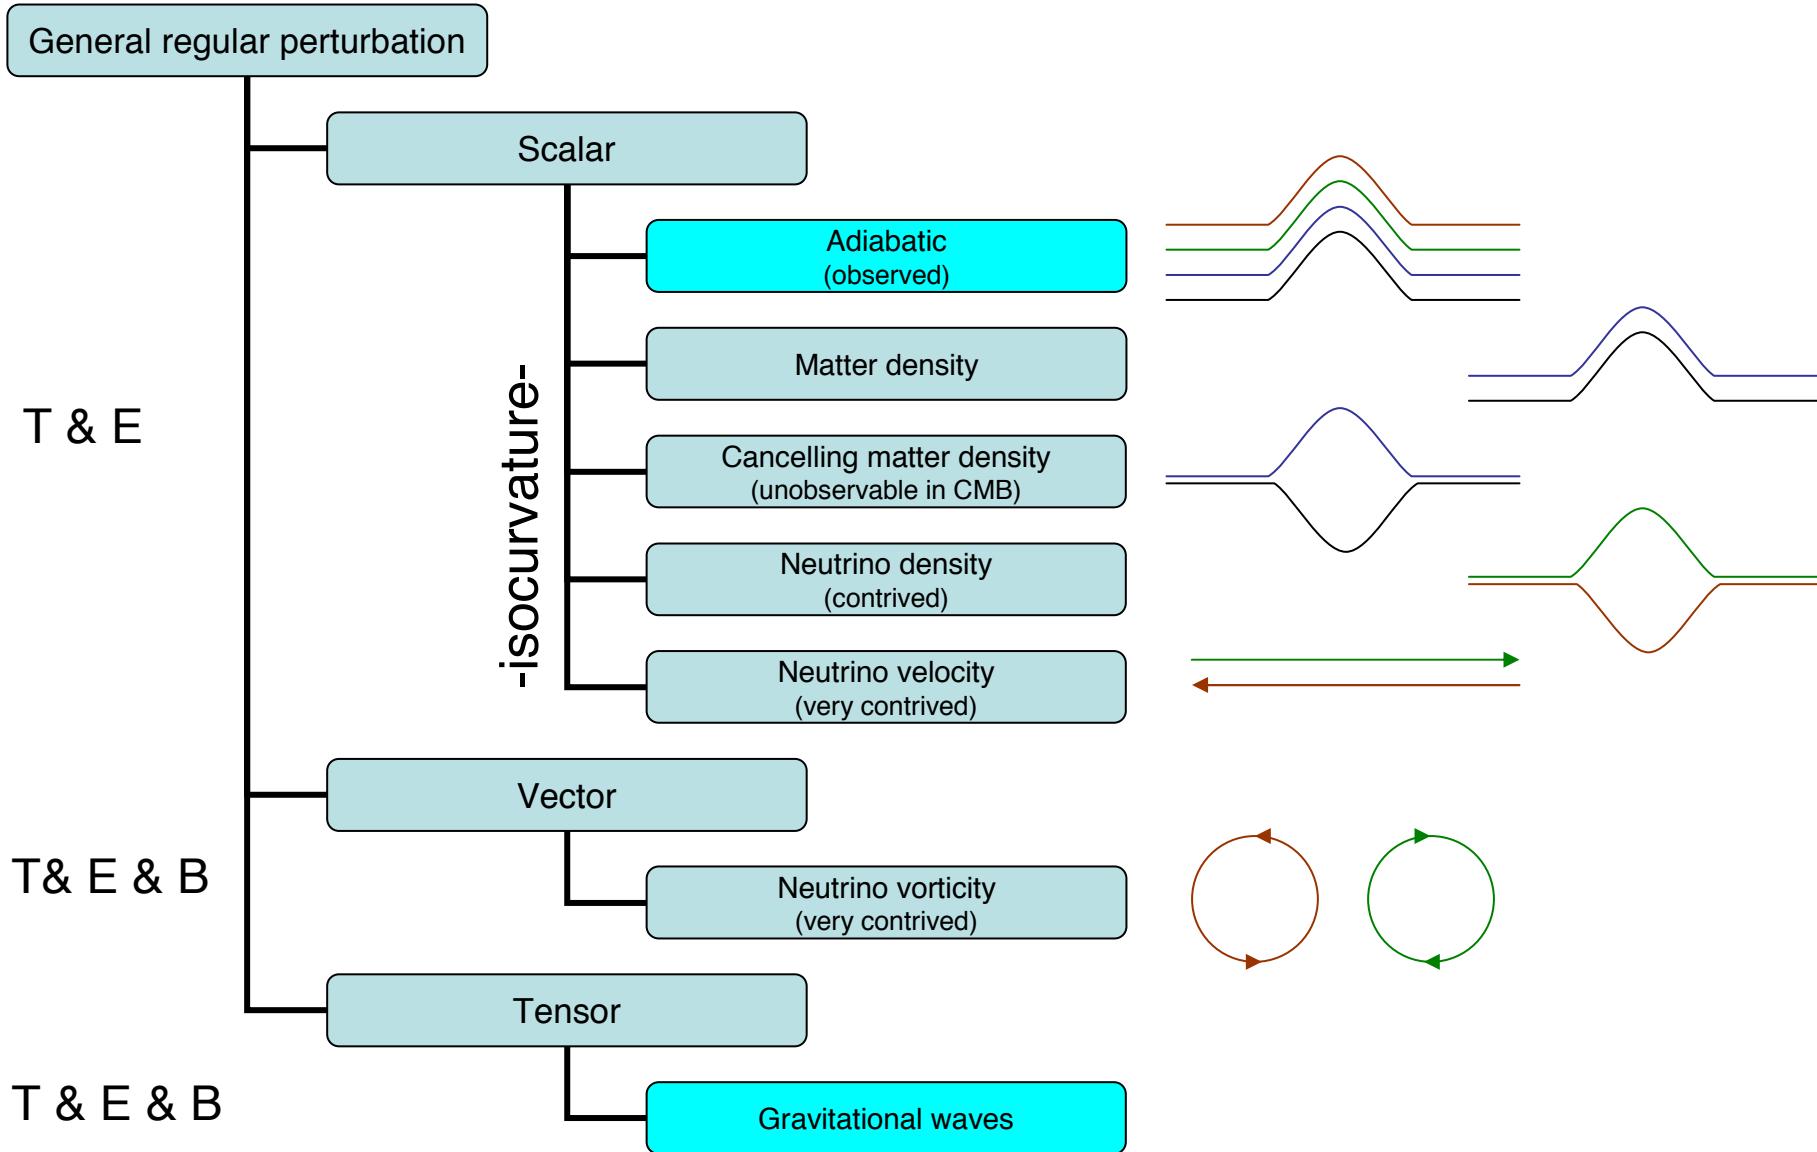

e.g. cold spot

“curl” modes  
B polarization

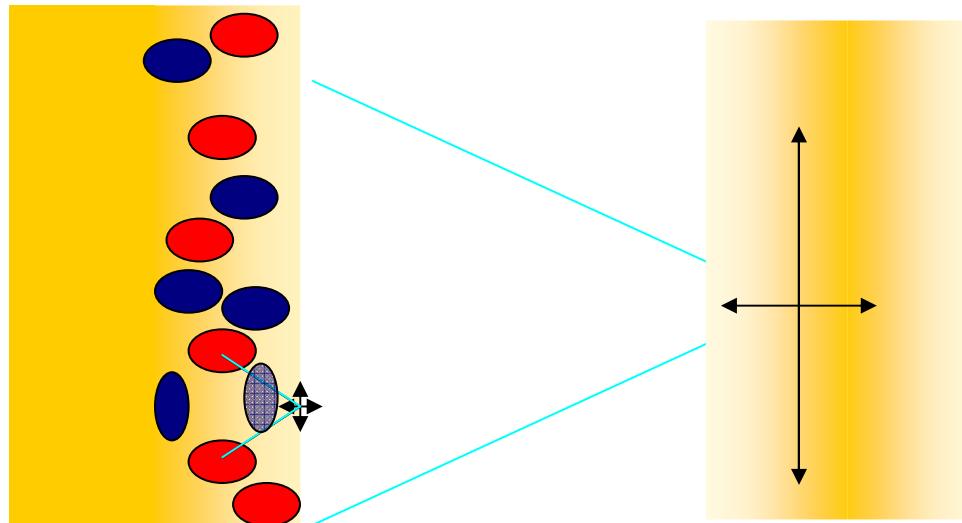

# What are the possible regular initial perturbations?

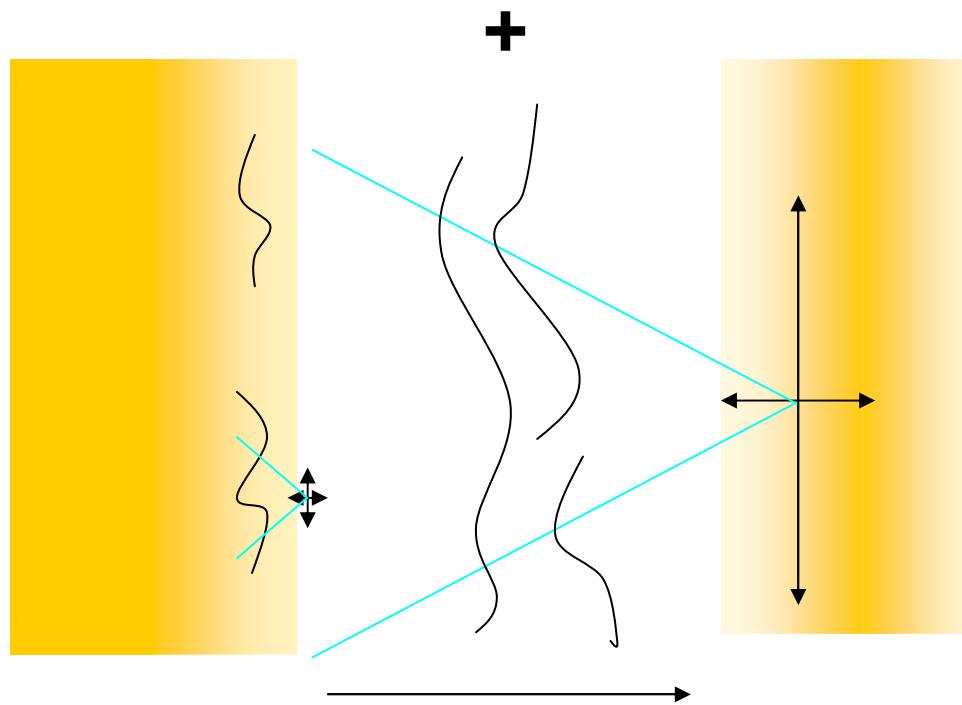

B modes only expected from gravitational waves and CMB lensing

Scalars

Tensors  
(unknown amplitude)

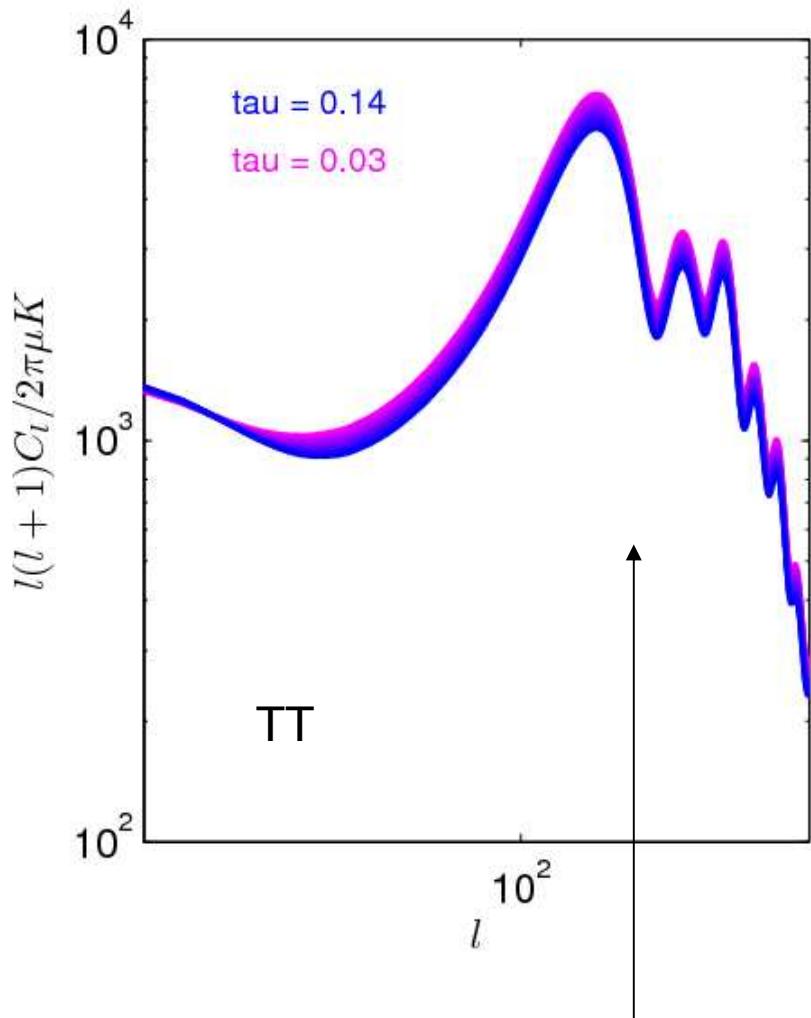

Quadrupole generated by anisotropic redshifting of LSS monopole  
by gravitational waves along the line of sight

## Scalar modes

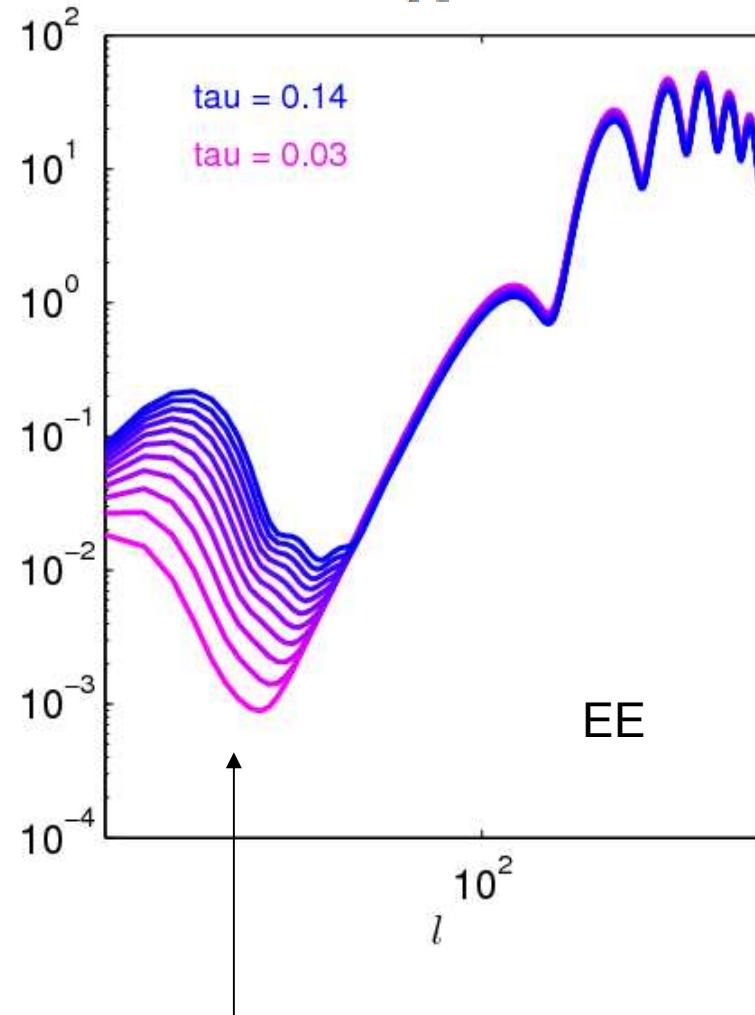

fraction  $\sim \tau$  of photons scatter at reionization

$$\tau = \int_0^{\eta_0} d\eta \, a n_e^{\text{reion}} \sigma_T$$

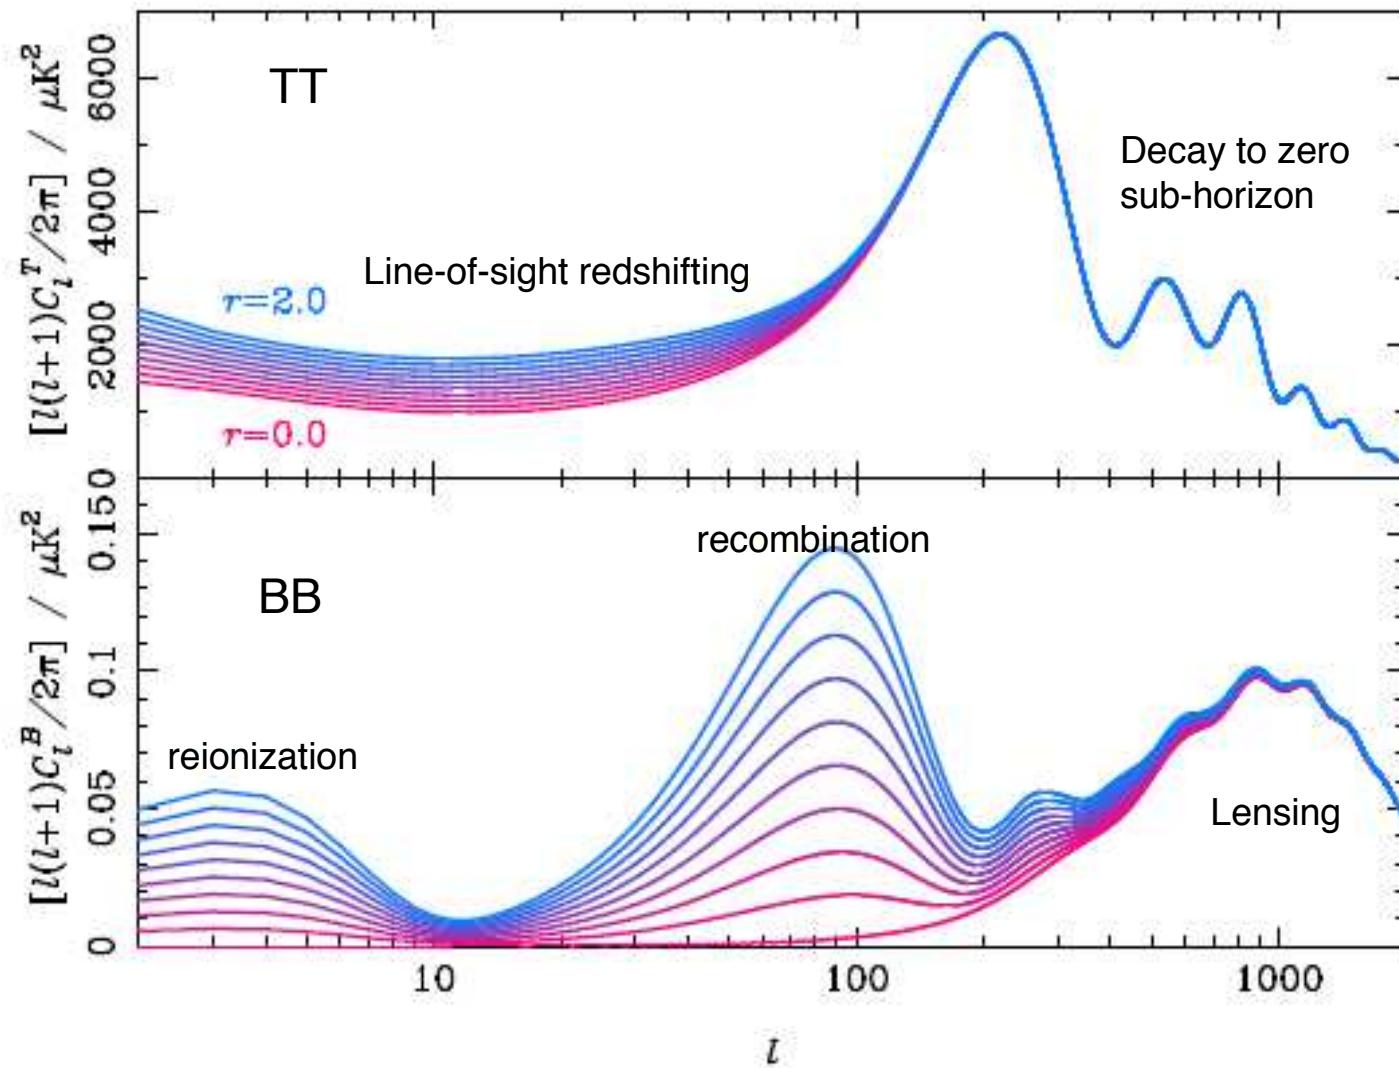

(also TE)

$e^{-2\tau}$  suppression

Quadrupole scattering at reionization  
 $\sim \tau^2$

## Effect of primordial gravitational waves

Current:  $r < 0.43$  from WMAP5  $\Delta T$  and  $E$  ( $r < 0.2$  with BAO + SN)

Thanks: Anthony Challinor

## WMAP: Polarization breaks large temperature-only degeneracies

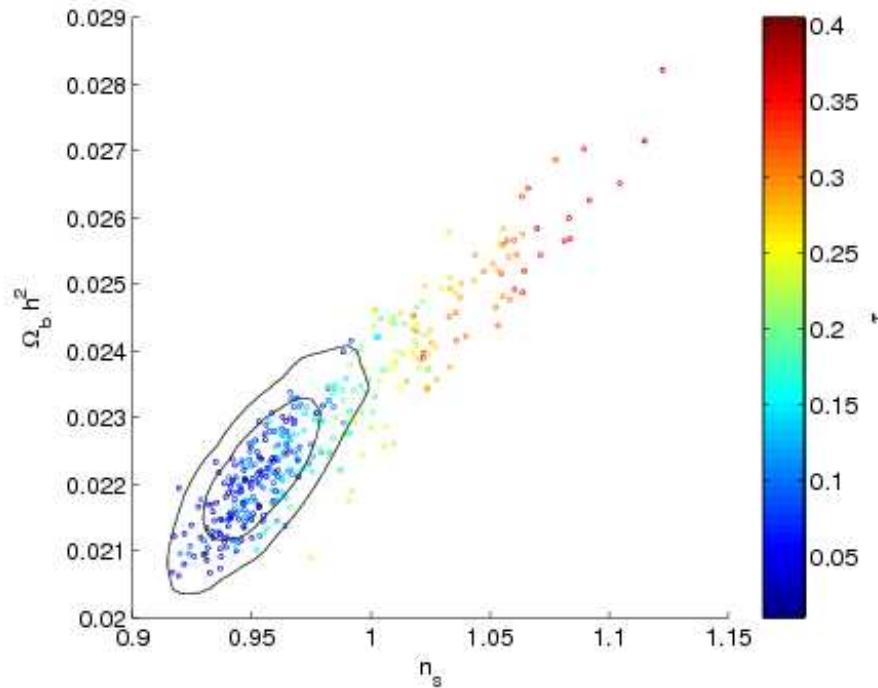

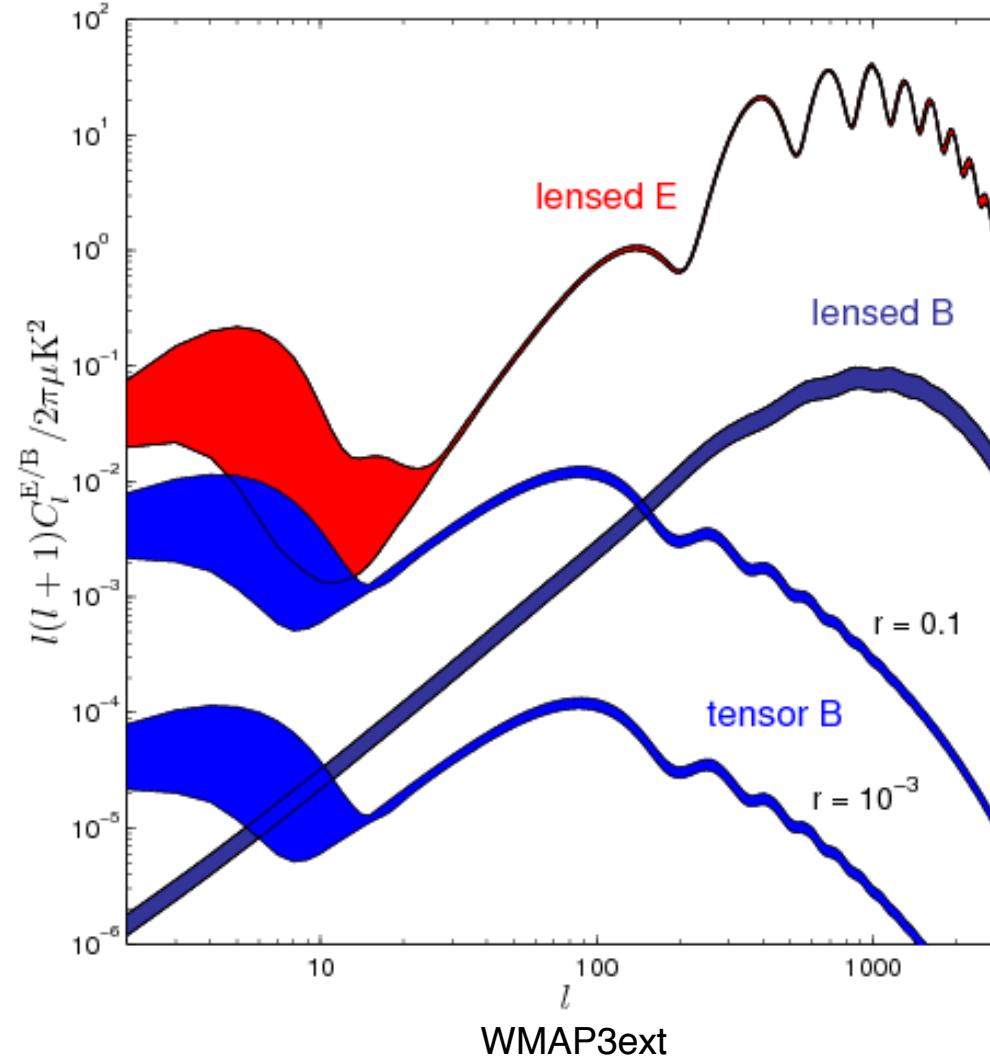

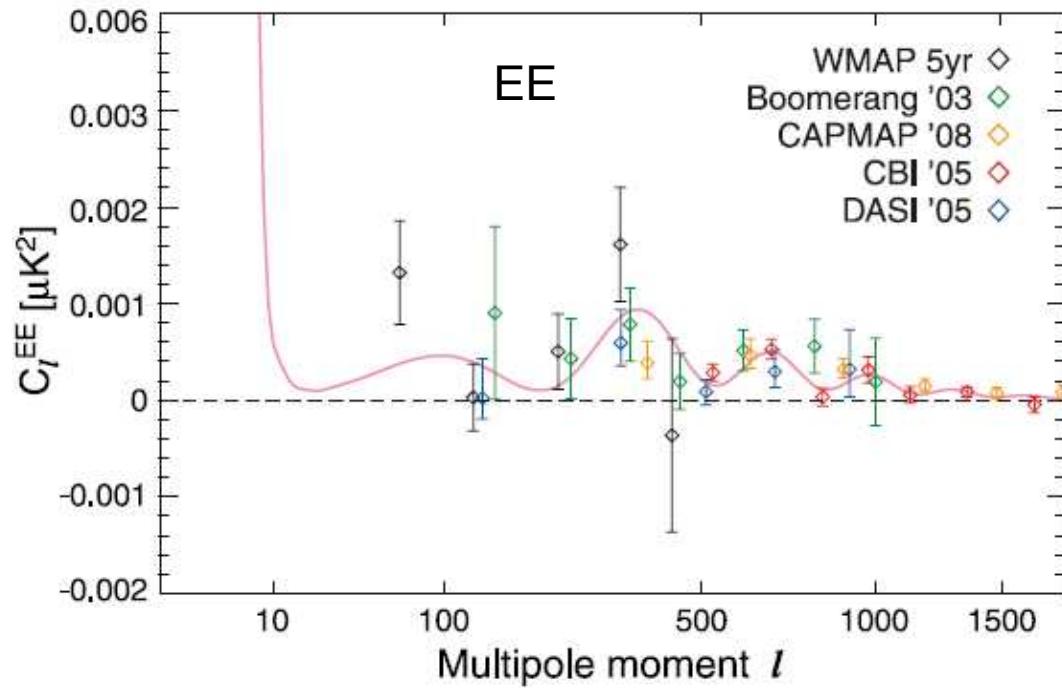

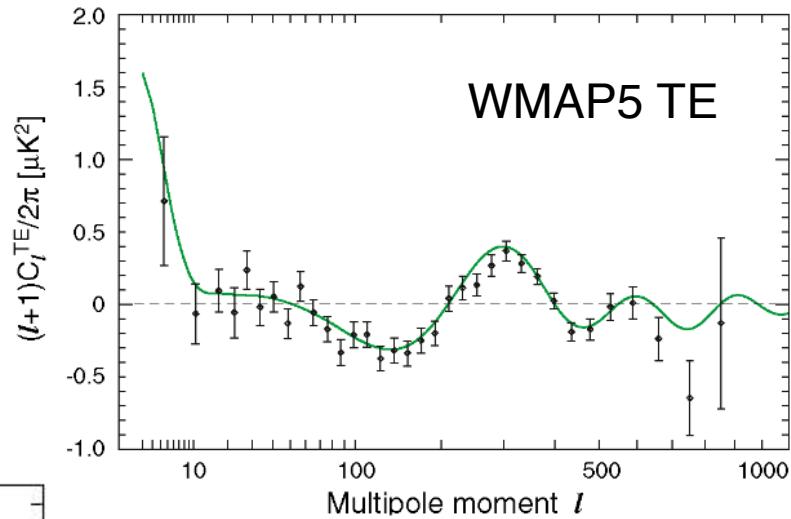

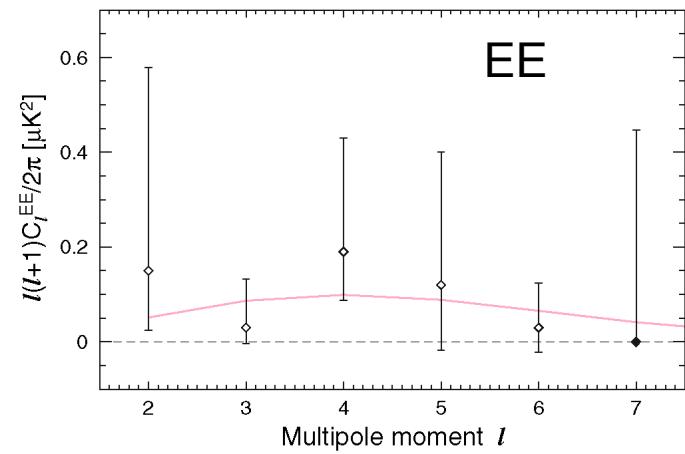

FIG. 1: Constraints from WMAP 3-year temperature (points) and joint with polarization (68% and 95% contours) for a basic six parameter  $\Lambda$ CDM model (no tensors). The points represent samples from the posterior distribution, and are coloured by the value of the optical depth  $\tau$ . Polarization constrains the optical depth, breaking the main flat-model degeneracy and suggesting  $n_s < 1$ .

Lewis: [astro-ph/0603753](https://arxiv.org/abs/astro-ph/0603753)

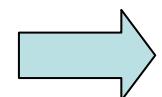

# CMB Polarization Predictions

95% indirect limits for LCDM given WMAP+2dF+HST+z<sub>re</sub>>6

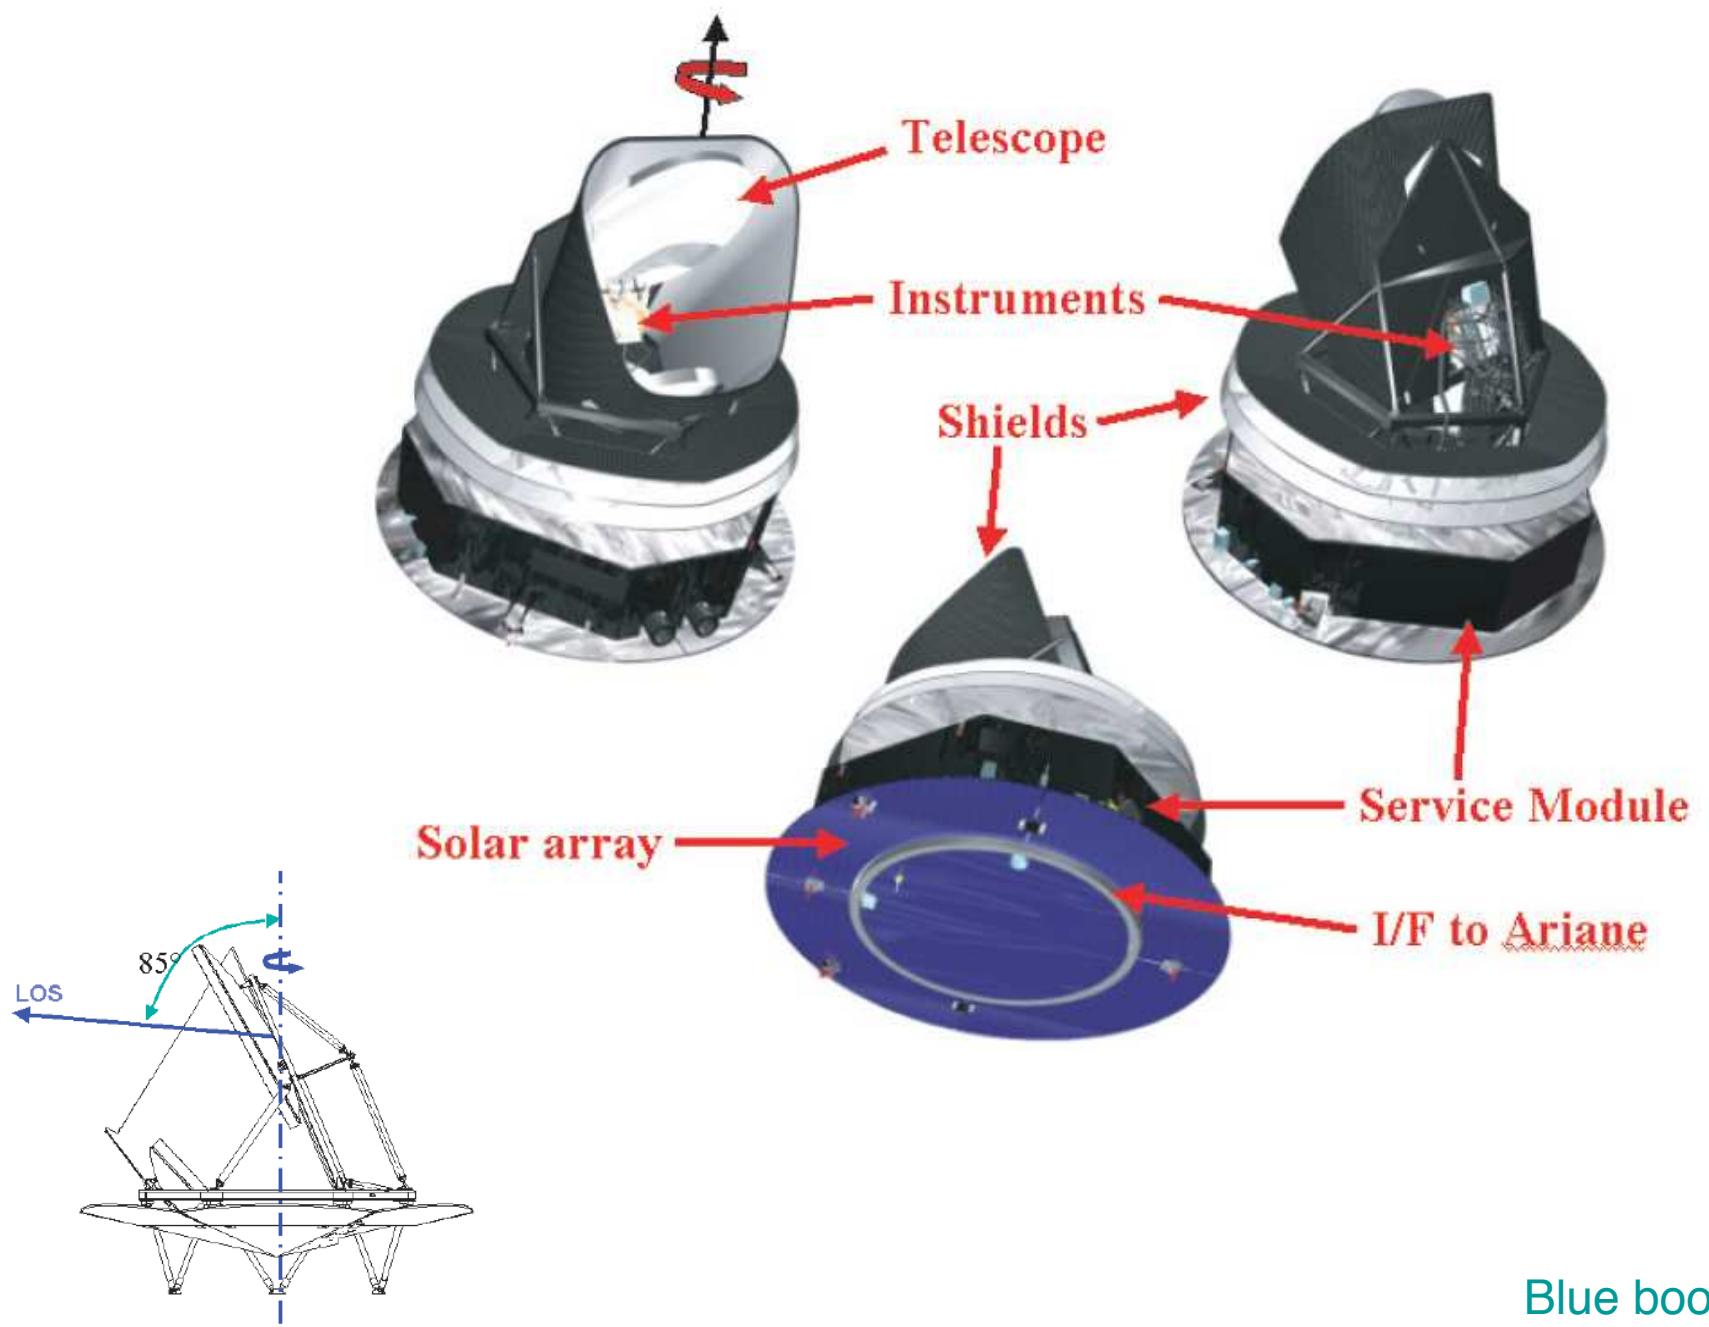

Nolta et al.

Currently only large scales useful for parameters  
(+ consistency check on small scales)

# PLANCK

- Third-generation CMB
- Measure linear temperature anisotropies to cosmic variance
- Polarization
- Launched 14<sup>th</sup> May 2009 (Ariane 5, from Kourou, French Guiana)
- Two instruments:
  - LFI – Reno Mandolesi
  - HFI – Jean-Loup Puget

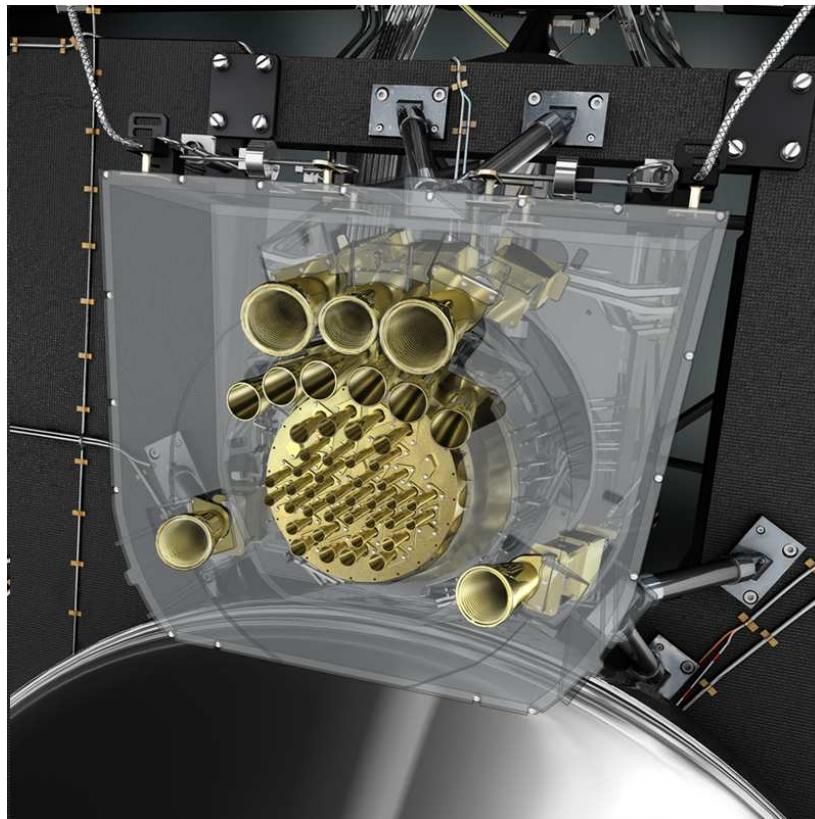

INSTRUMENT CHARACTERISTIC	LFI			HFI					
	HEMT arrays			Bolometer arrays					
Detector Technology.....	HEMT arrays						Bolometer arrays		
Center Frequency [GHz].....	30	44	70	100	143	217	353	545	857
Bandwidth ( $\Delta\nu/\nu$ ) .....	0.2	0.2	0.2	0.33	0.33	0.33	0.33	0.33	0.33
Angular Resolution (arcmin) .....	33	24	14	10	7.1	5.0	5.0	5.0	5.0
$\Delta T/T$ per pixel (Stokes $I$ ) <sup>a</sup> .....	2.0	2.7	4.7	2.5	2.2	4.8	14.7	147	6700
$\Delta T/T$ per pixel (Stokes $Q$ & $U$ ) <sup>a</sup> ...	2.8	3.9	6.7	4.0	4.2	9.8	29.8	...	...

<sup>a</sup> Goal ( $\mu\text{K}/\text{K}$ ,  $1\sigma$ ), 14 months integration, square pixels whose sides are given in the row “Angular Resolution”.

## DISTANT OUTPOST: HERSCHEL AND PLANCK IN ORBIT

Corrections to stay in Lissajous L2 orbit every 30 days

- Spacecraft rotates at 1 rpm
- Optic axis at 85° traces large circles on the CMB  
(small precession to cover whole sky)
- Re-points every hour

5-10 arcmin beam  
(HFI)

Full sky every 6-7 months: first 2, then hopefully 4 full scans

# Current Status

- Orbiting L2; HFI detectors at operational temperature  $\sim 0.1\text{K}$  (coolest known objects in space!)
- LFI and HFI declared to be fully and optimally tuned; meet predicted performance
- 13<sup>th</sup> August: First Light Survey (2 weeks) calibration running into first sky survey (starting 27<sup>th</sup> August)
  - dipole measurement in 1 degree strip

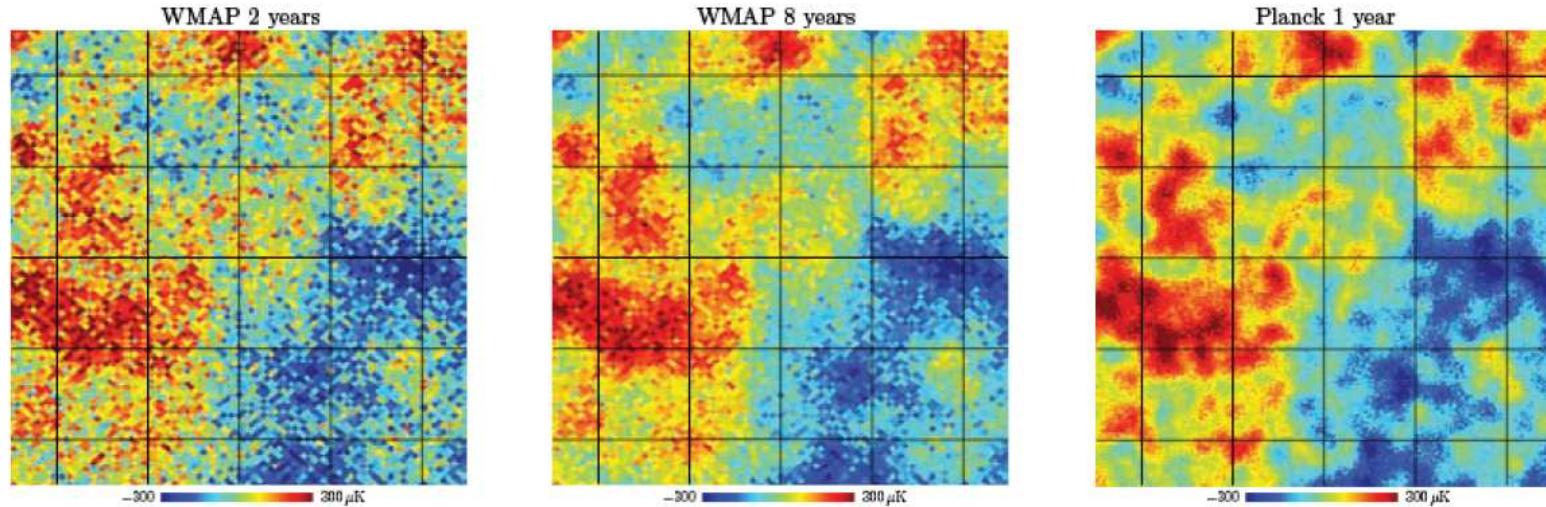

So far, so good!

## Timetable

	Duration (months)	Date
Launch	0	5/2009
Cruise, cooldown, checkout	3	7/2009
First sky survey	6	1/2010
Second sky survey	6	7/2010
→ ERCSC (based on first survey)		7/2010
Analyse first-year data	24	
First-year results released		7/2012
Extended mission	TBD	

**(Early Release Compact Source Catalogue)**

## Planck vs WMAP

30–857 GHz cf 23–94 GHz (WMAP)

3× resolution

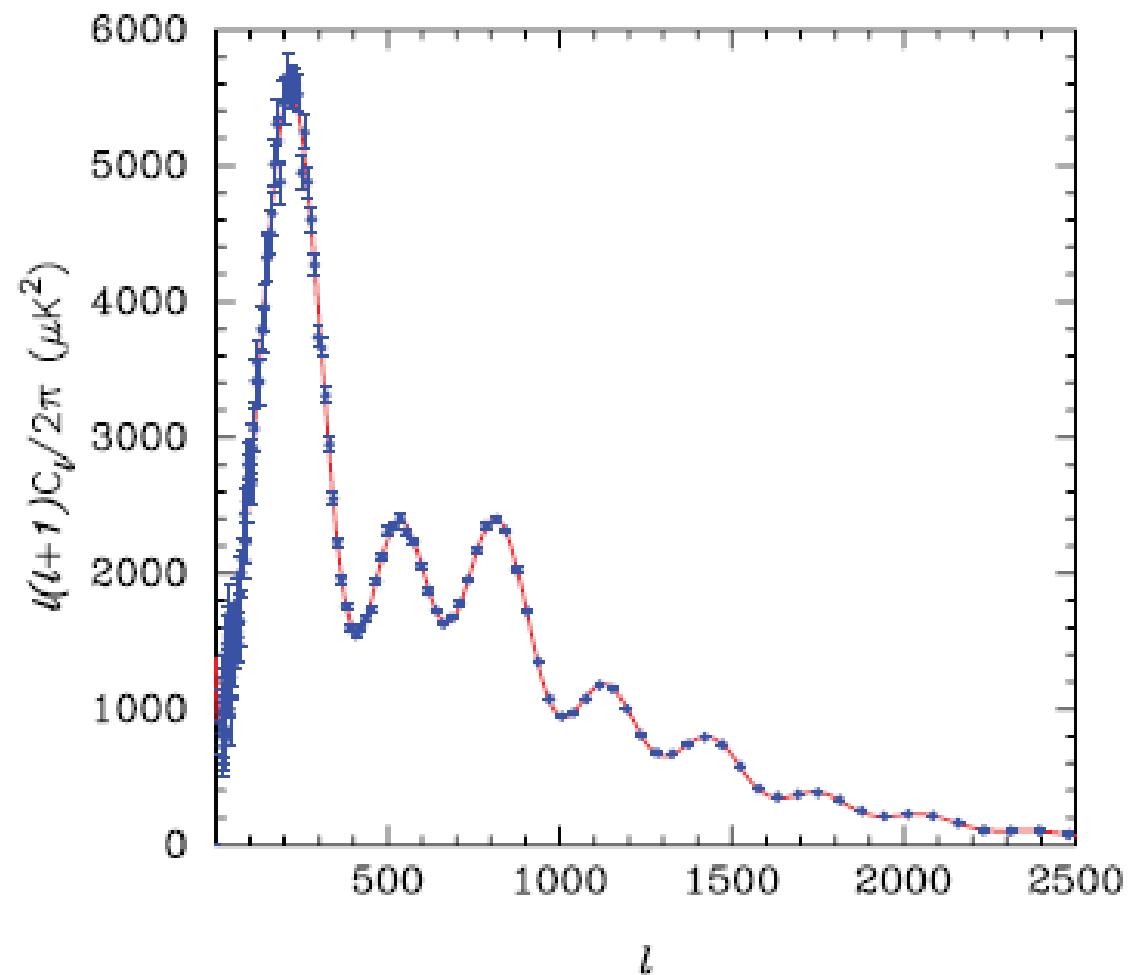

~ 20× instantaneous sensitivity

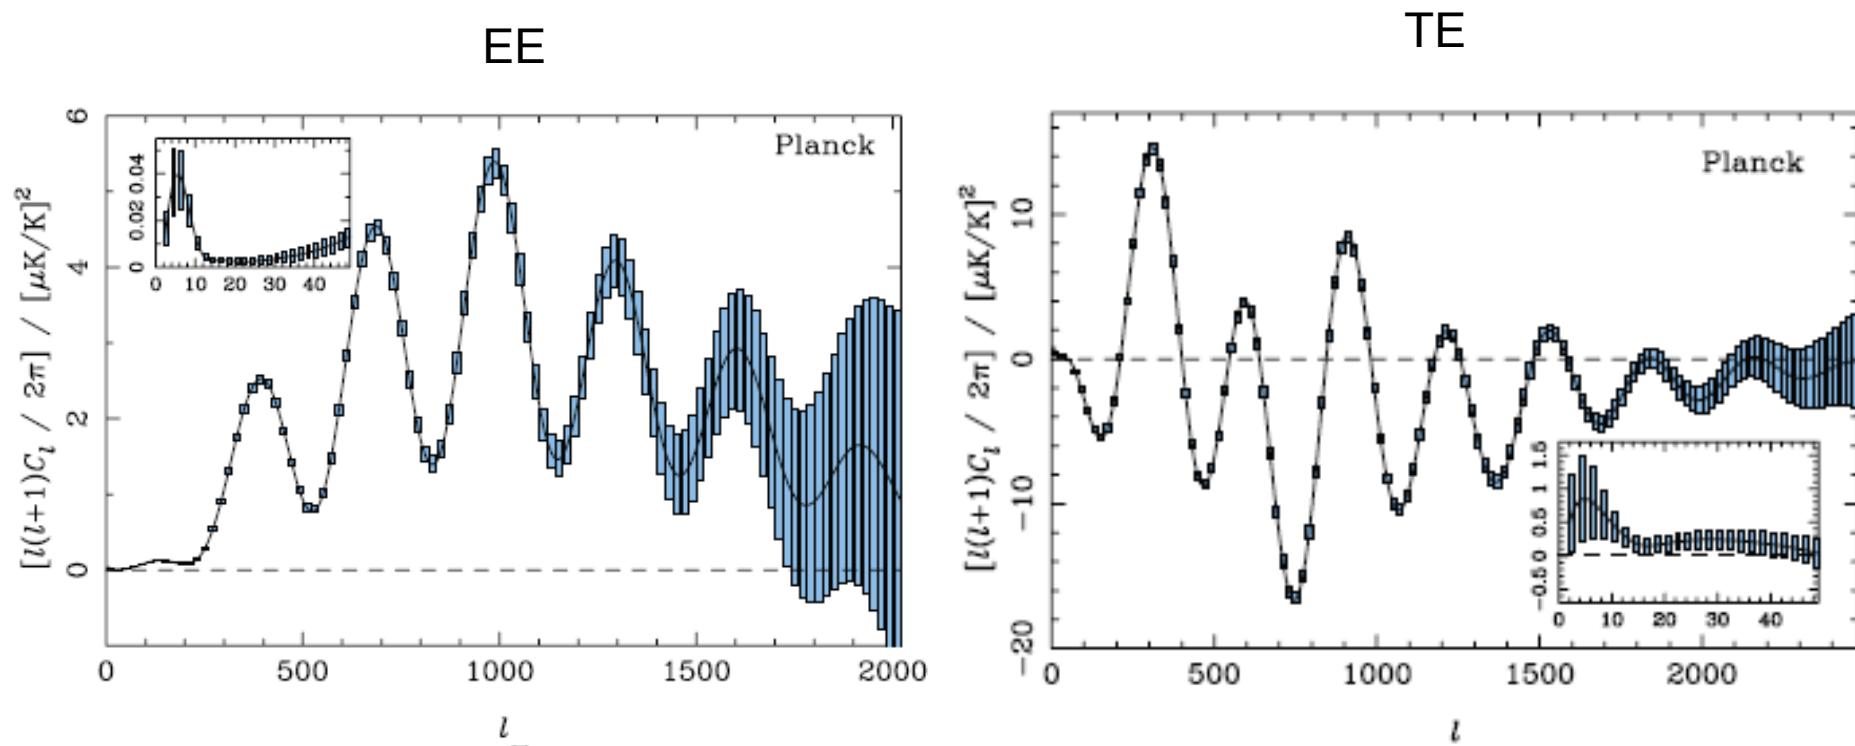

- Nominal Planck survey 7× sensitivity of WMAP8

$\Delta T$  cosmic-variance limited to  $l \sim 2000$

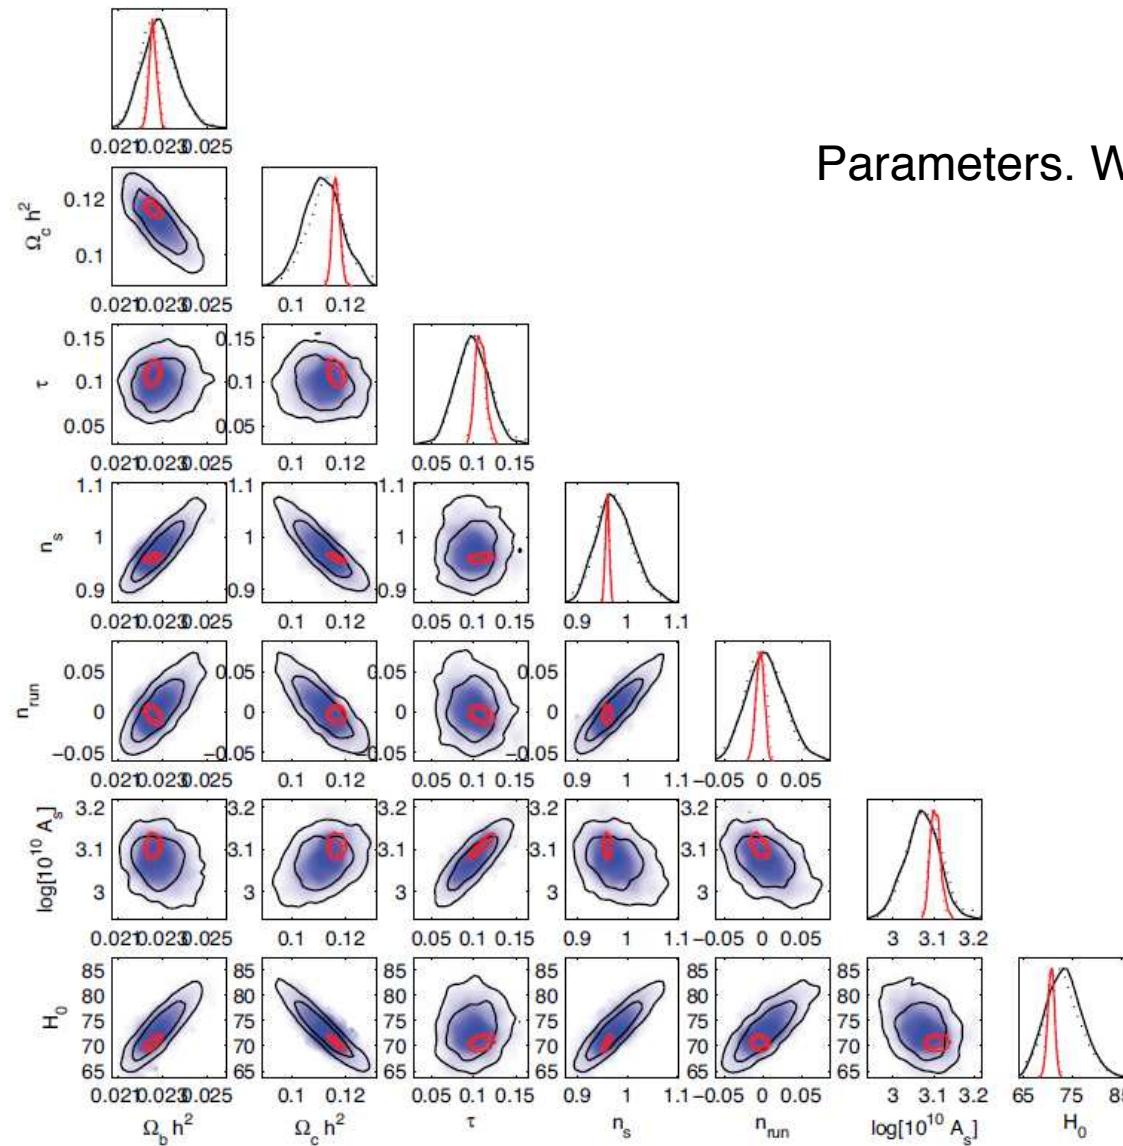

Temperature almost cosmic variance limited until secondaries dominate

'Blue book' forecast

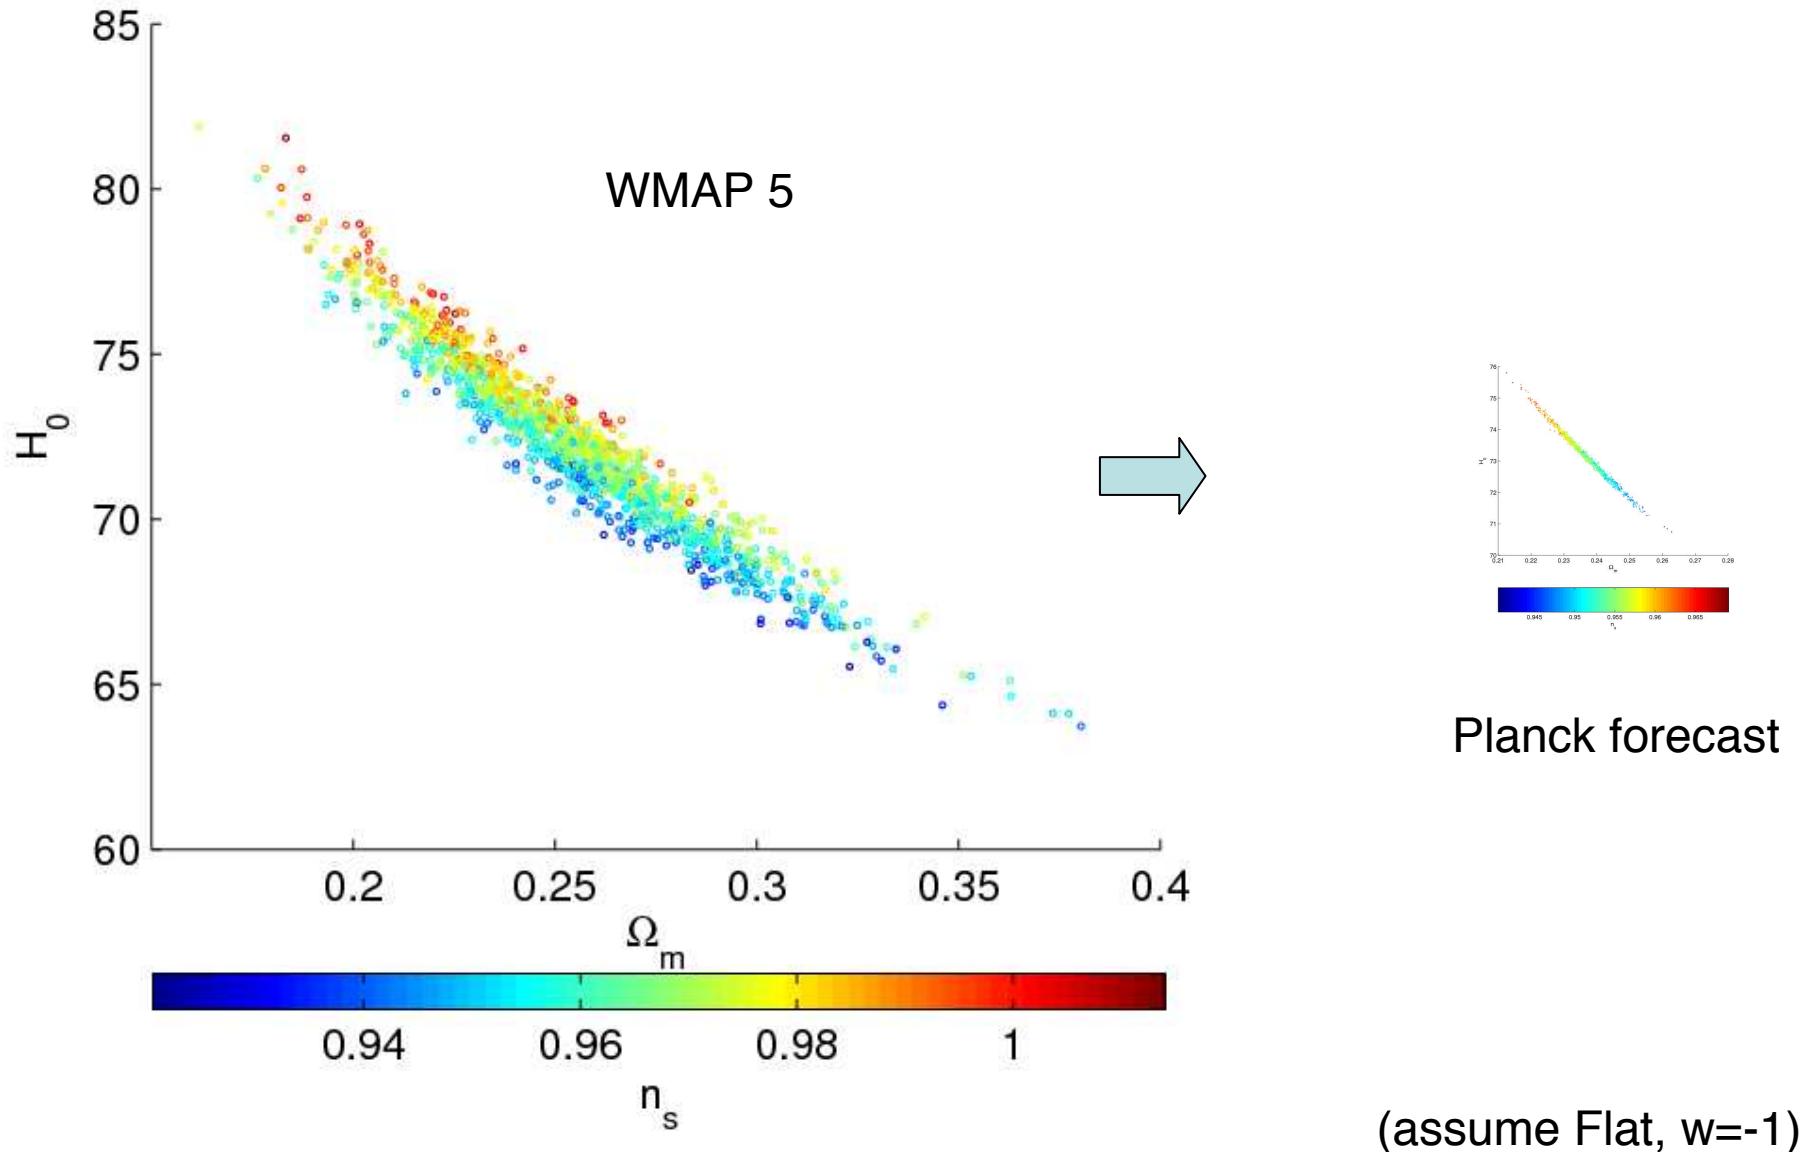

- small scales only slight help with parameters
- but allows important consistency cross-checks (less SZ in EE)
- Large scales crucial for optical depth constraint

Parameters. WMAP4 vs Planck

FIG 2.18.—Forecasts of 1 and 2 $\sigma$  contour regions for various cosmological parameters when the spectral index is allowed to run. Blue contours show forecasts for WMAP after 4 years of observation and red contours show results for Planck after 1 year of observations. The curves show marginalized posterior distributions for each parameter.

Degeneracies with other parameters – still benefit from combining with other data

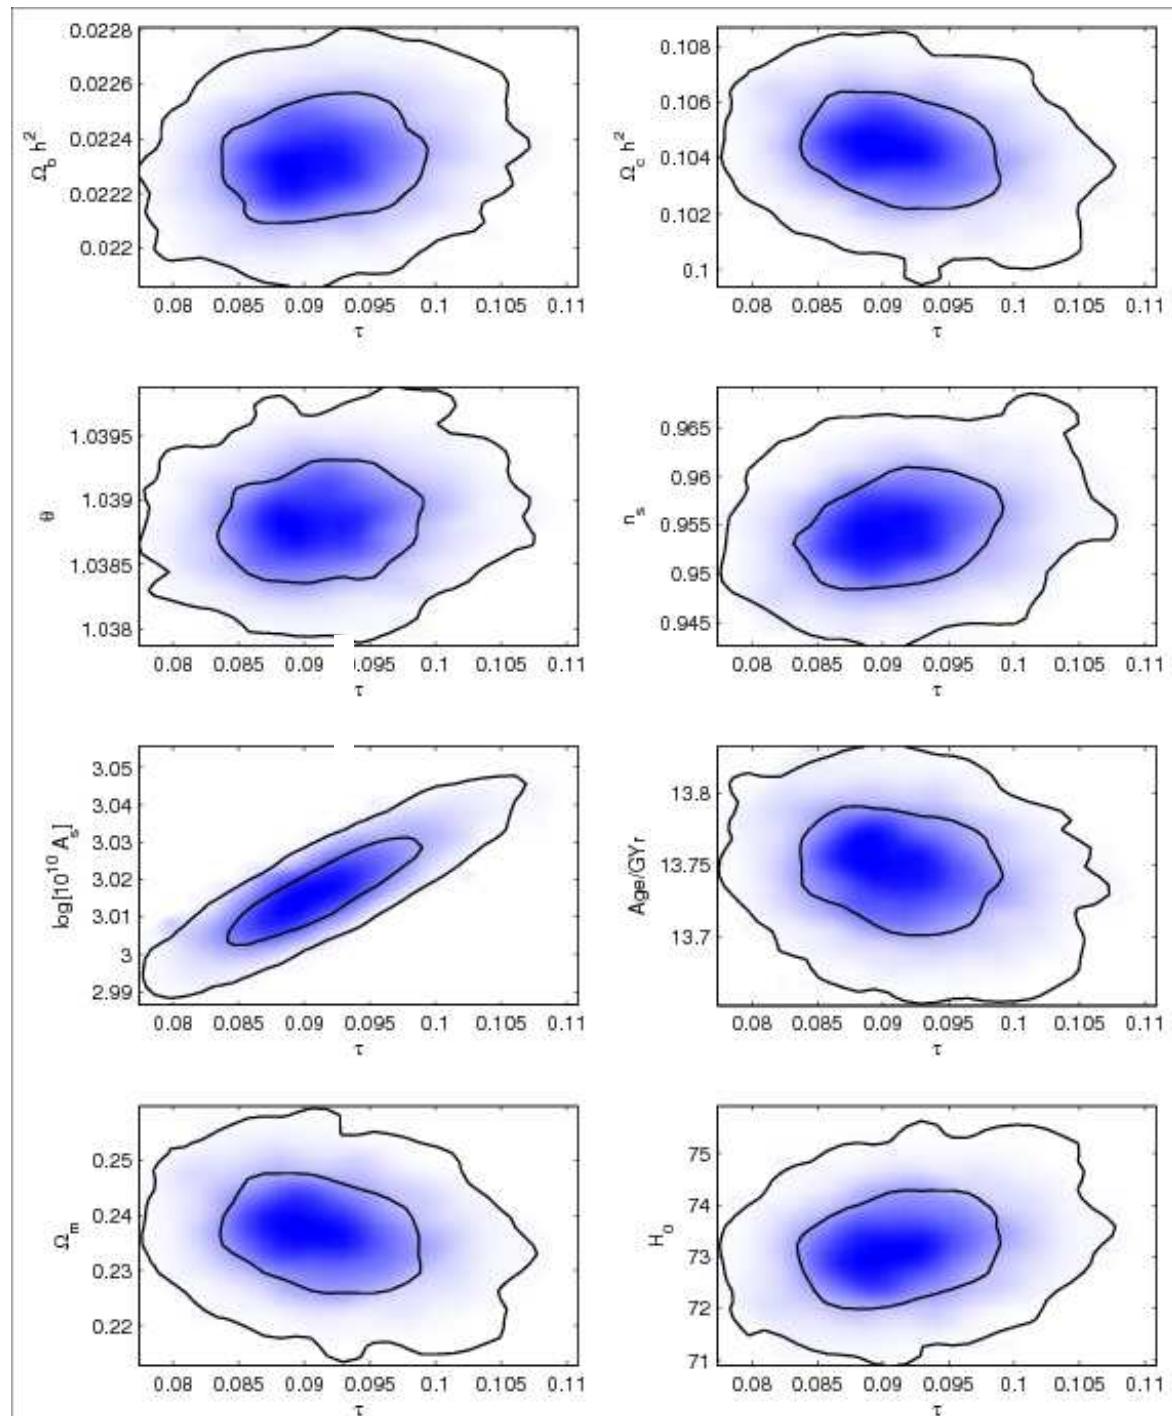

Planck optical depth  
constraints

Marginalized:  
 $\tau \sim X \pm 0.005$

c.f. WMAP  
 $\tau \sim 0.09 \pm 0.017 \pm 0.01$

Small scale  $C_l \sim A_s e^{-2\tau}$

# Default reionization ( $x_e$ ) parameterization

$$\tau = \int_0^{\eta_0} d\eta a n_e^{\text{reion}} \sigma_T$$

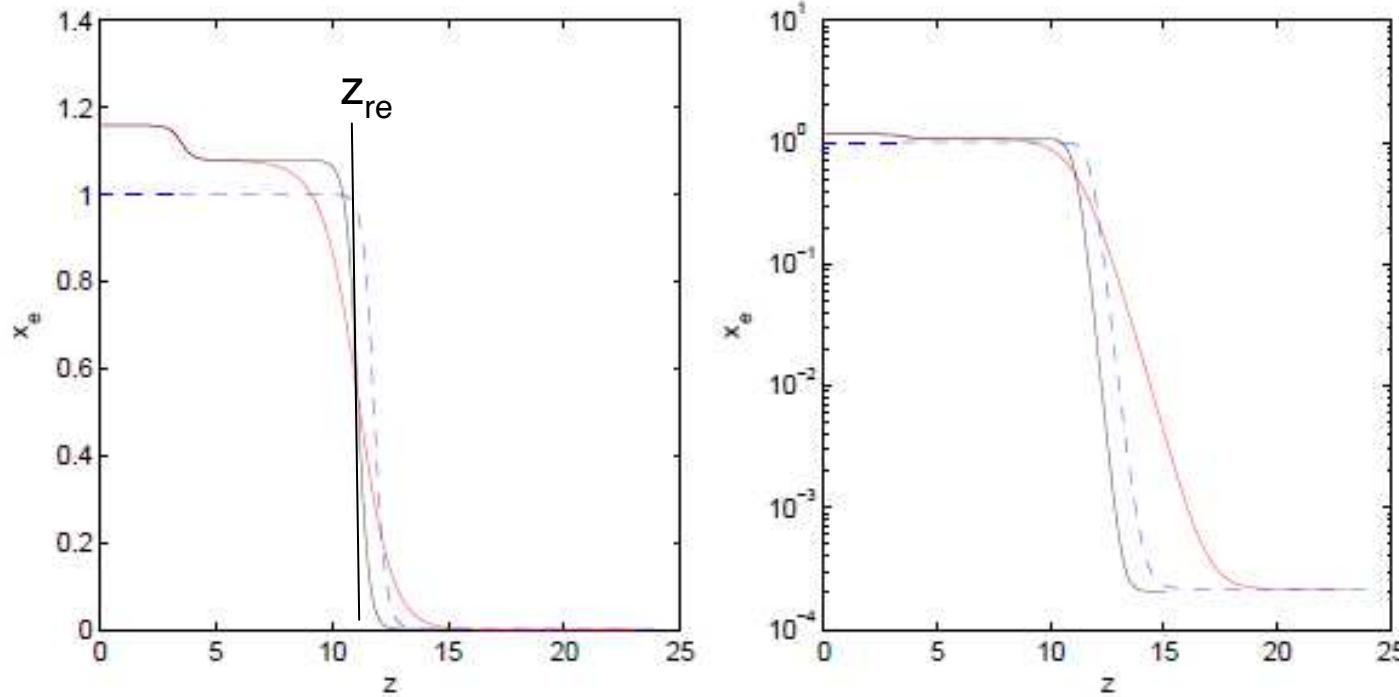

FIG. 6: Three recombination histories all with  $\tau = 0.09$ . The dashed line is the model typically used by CMBFAST and CAMB prior to March 2008 with  $f = 1$ . The black line is the new model with  $\Delta_z = 0.5$ , the red line with  $\Delta_z = 1.5$ .

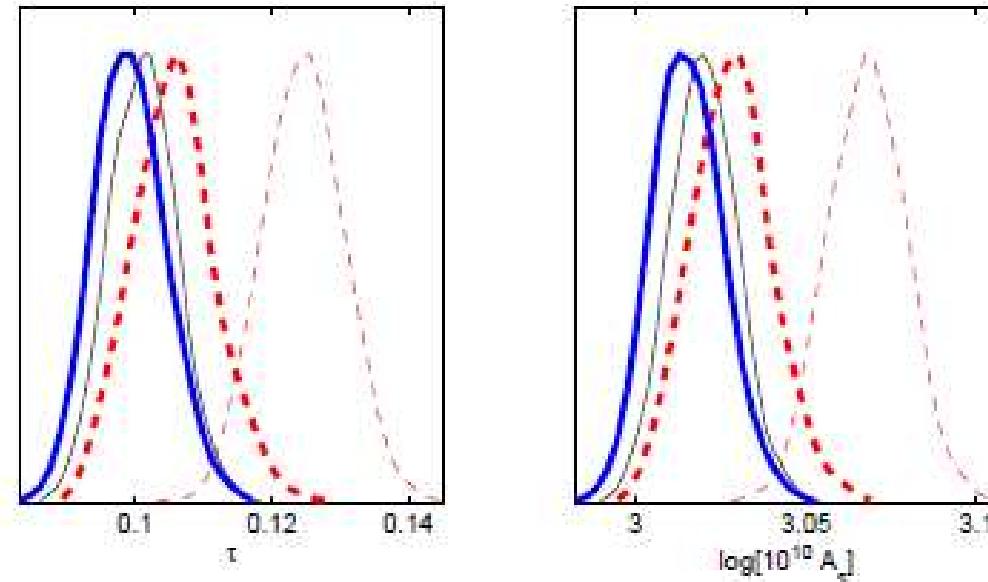

$$x_e(y) = \frac{f}{2} \left[ 1 + \tanh \left( \frac{y - y(z_{\text{re}})}{\Delta_y} \right) \right]$$

CAMB's default parameterization  
as of March 2008: <http://camb.info/>

$$y(z_{\text{re}}) = (1+z_{\text{re}})^{3/2} \quad f = 1 + f_{H_e}$$

History may matter too...

Potentially bias tau, hence  $A_s$  (hence  $\sigma_8$ ) if we assume the wrong reionization history

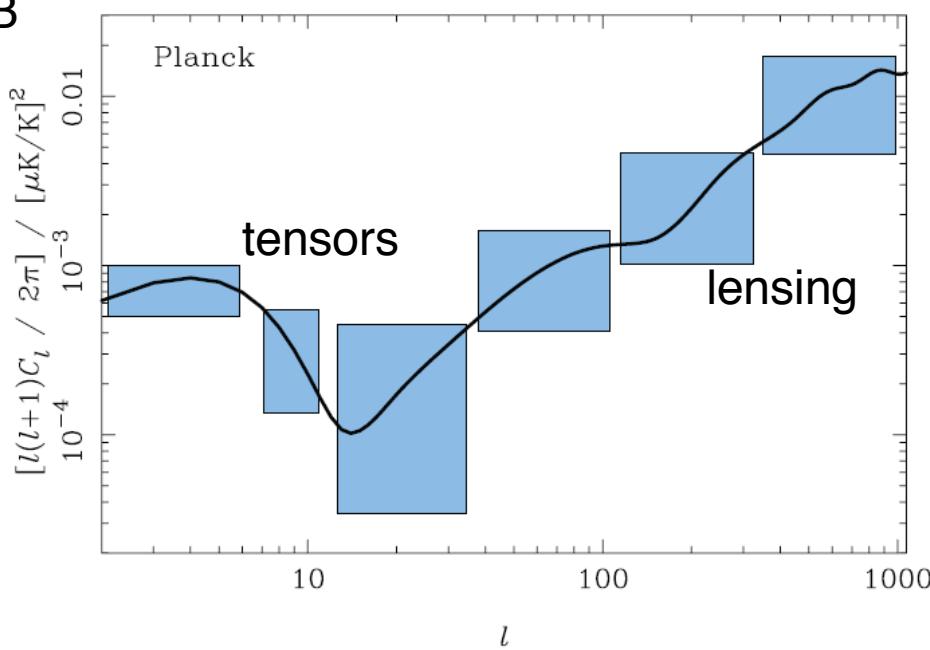

Lewis,Weller,Battye  
astro-ph/0606552

**Figure 6.** PLANCK optical depth and amplitude constraints from the sharp model analysed using the sharp model (thin solid), the incorrect result from analysing a double reionization model using a sharp model (thin dashed), and the consistent result from the double reionization (thick dashed) and sharp (thick solid) models using a binned reconstruction.

- good physically-motivated parameterizations useful!

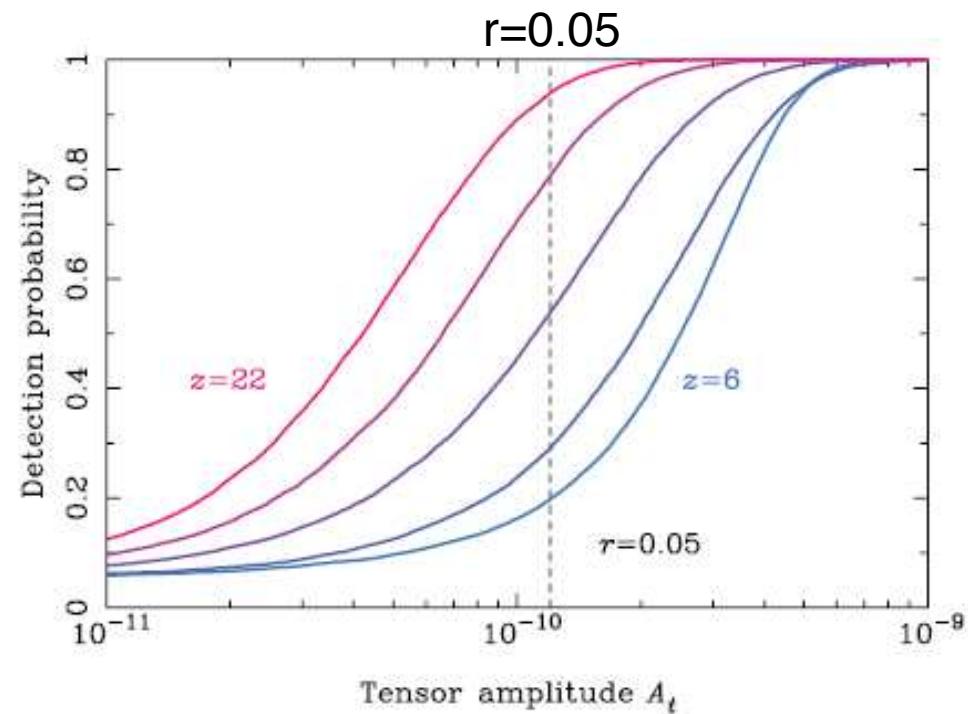

See Jochen's talk..

BB

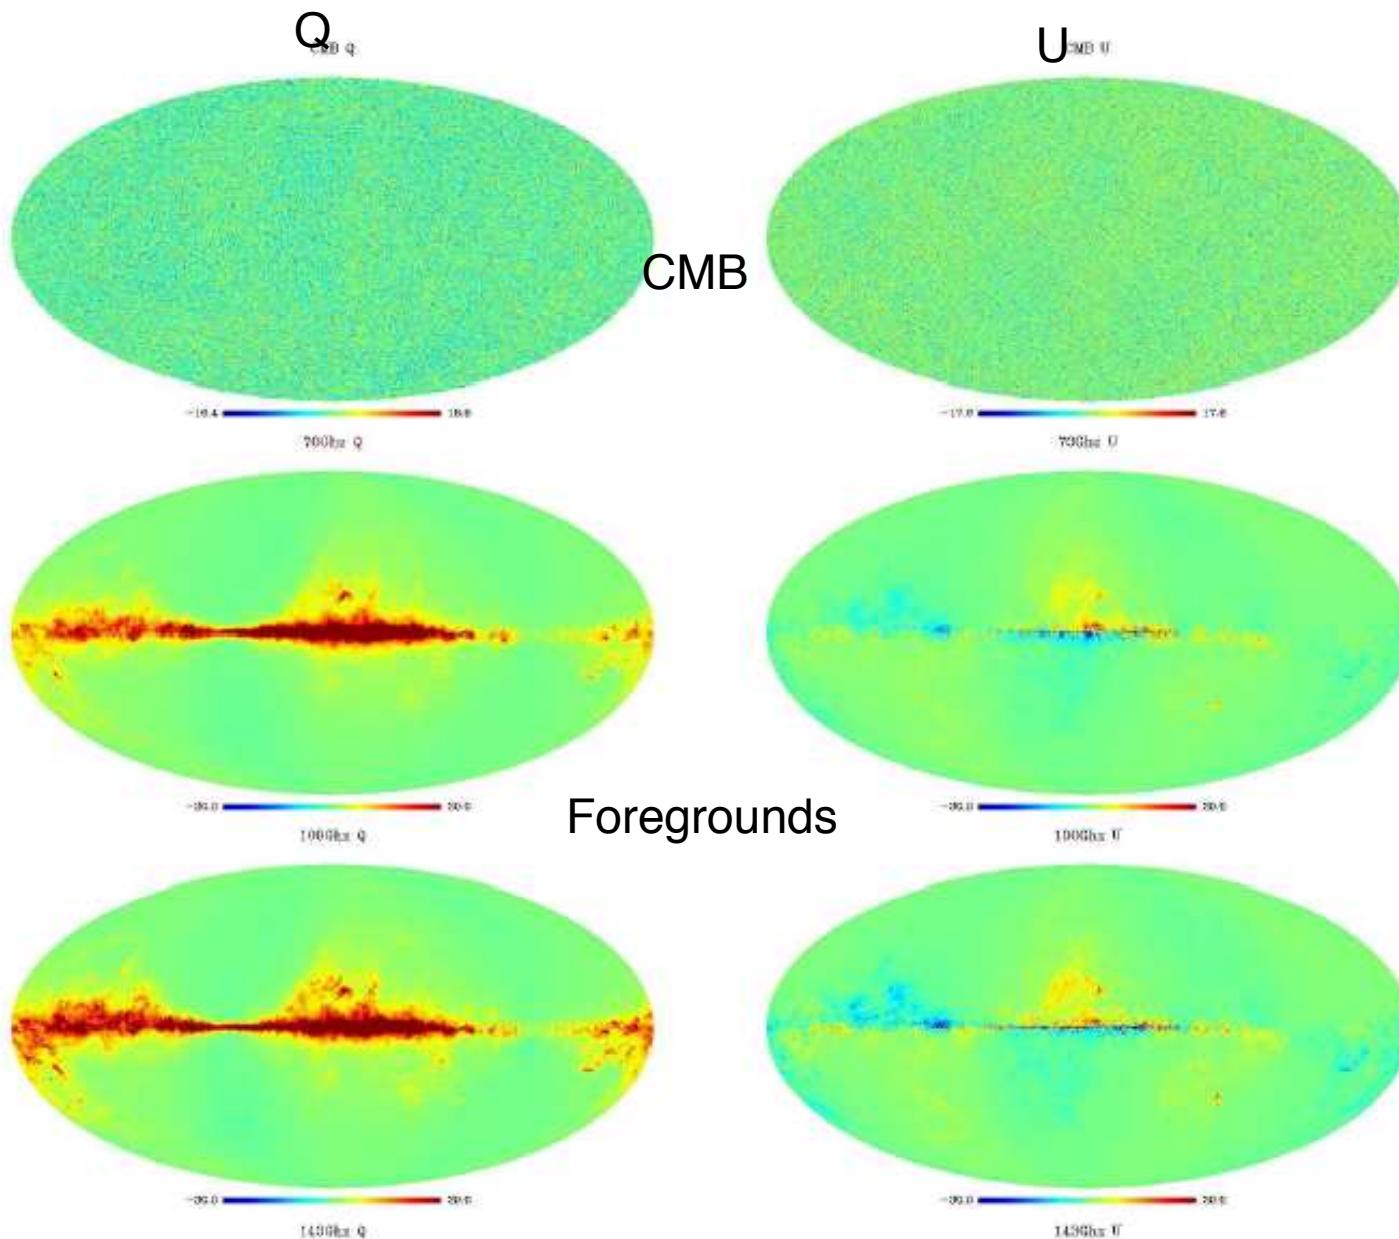

Reionization optical depth effects primordial tensor amplitude that can be detected

- Some constraints from lensing
- Chance to detect primordial gravitational waves
- Also all gravitational wave signal detectable by Planck is from reionization

## BUT: Big foregrounds on large scales

Pure-CMB  
Simulation

70GHz

Foregrounds

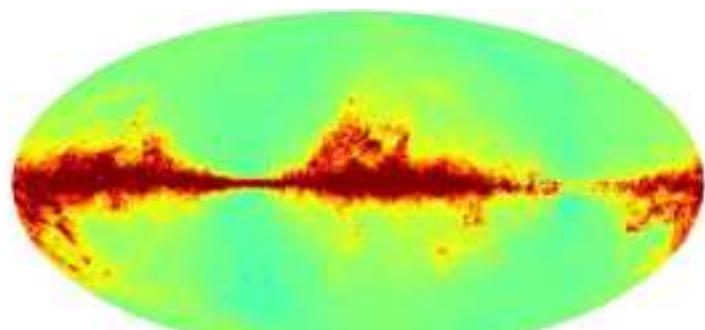

100GHz

143GHz  $Q$

143GHz  $U$

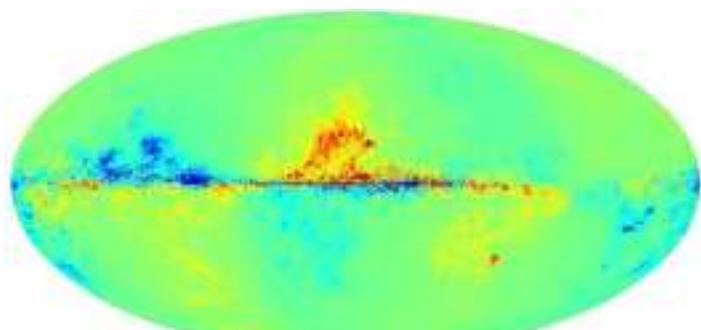

Efstathiou et al 2009

Q

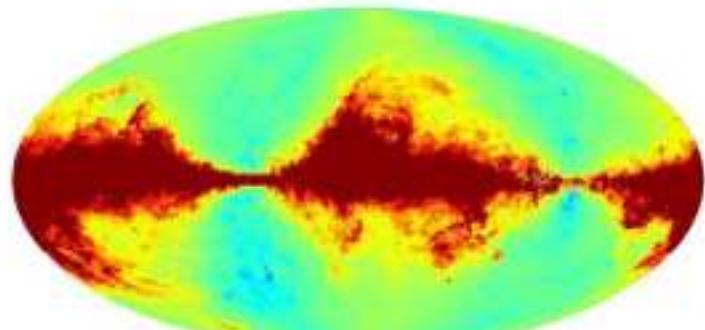

-30.0 — 30.0  
217Ghz, Q

U

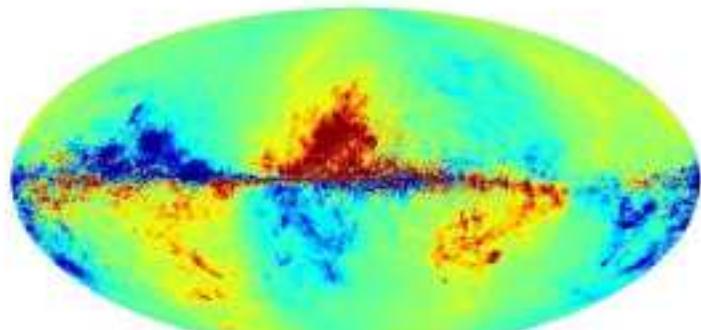

-30.0 — 30.0  
217Ghz, U

143Ghz

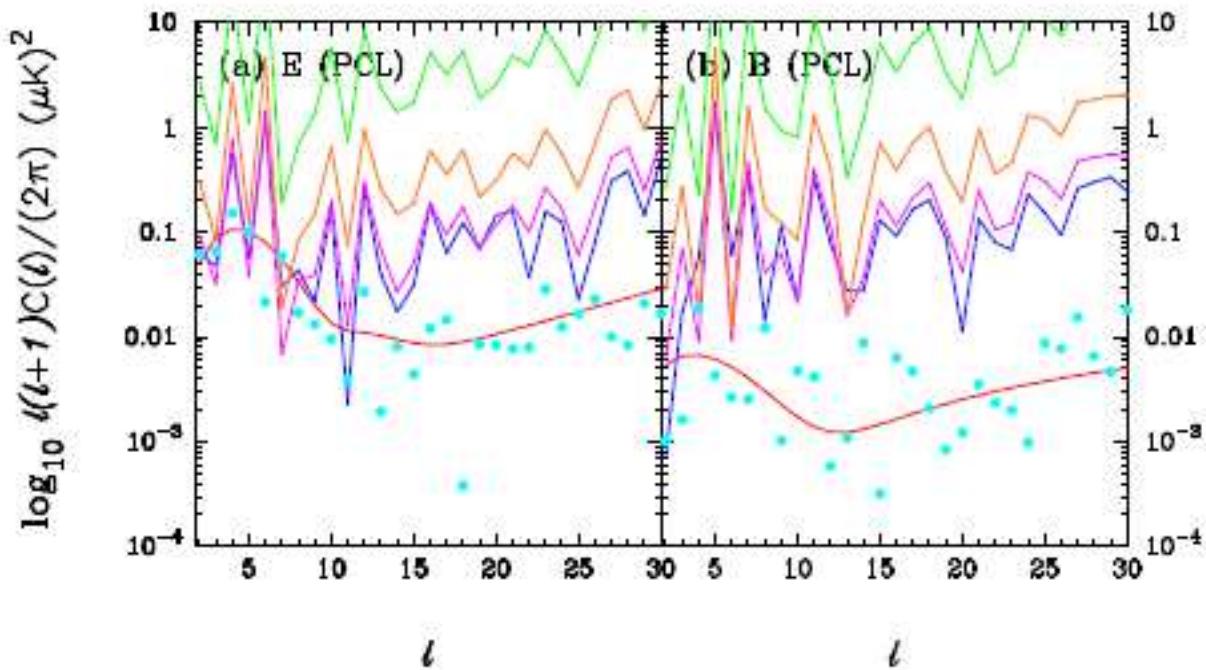

-30.0 — 30.0  
217Ghz, Q

217Ghz

-30.0 — 30.0  
217Ghz, U

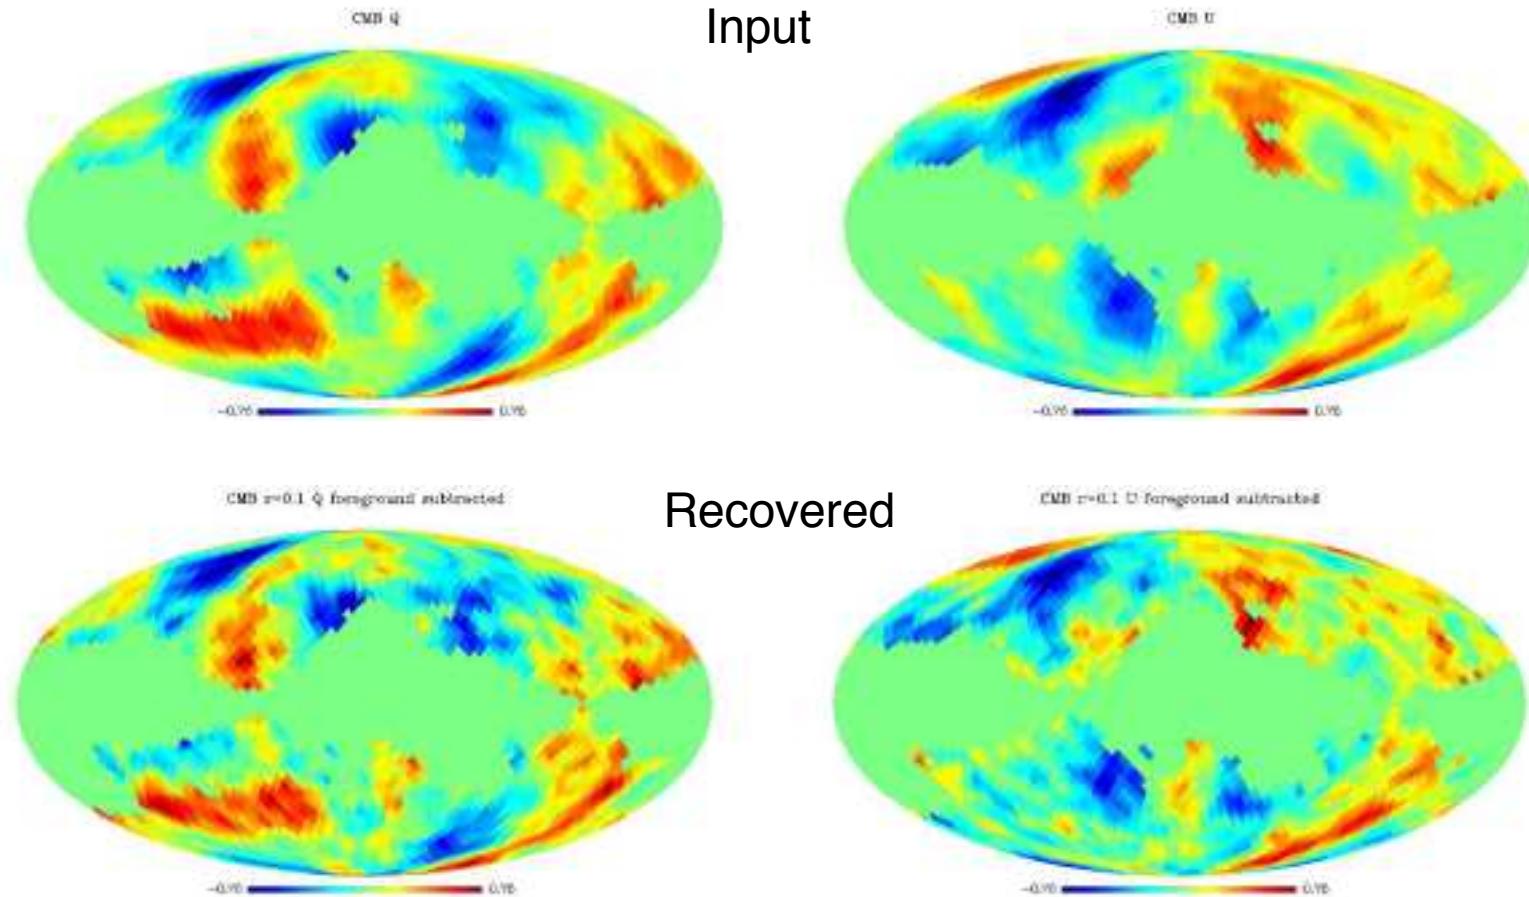

Efstathiou et al 2009

**Figure 4.** PCL  $E$  and  $B$ -mode power spectrum estimates computed for the CMB simulations and foreground components of Figure 1. The power spectra are computed for the region of the sky outside the internal mask. No instrumental noise has been added to the simulations. The blue points show the power spectrum estimates for the CMB. The red lines show the theoretical input CMB spectra. The foreground power spectra are as follows: 70 GHz (dark blue); 100 GHz (purple); 143 GHz (orange); 217 GHz (green).

Foregrounds very important for reionization and tensor mode studies

- Use assumed blackbody spectrum to subtract foregrounds

B-mode constraint

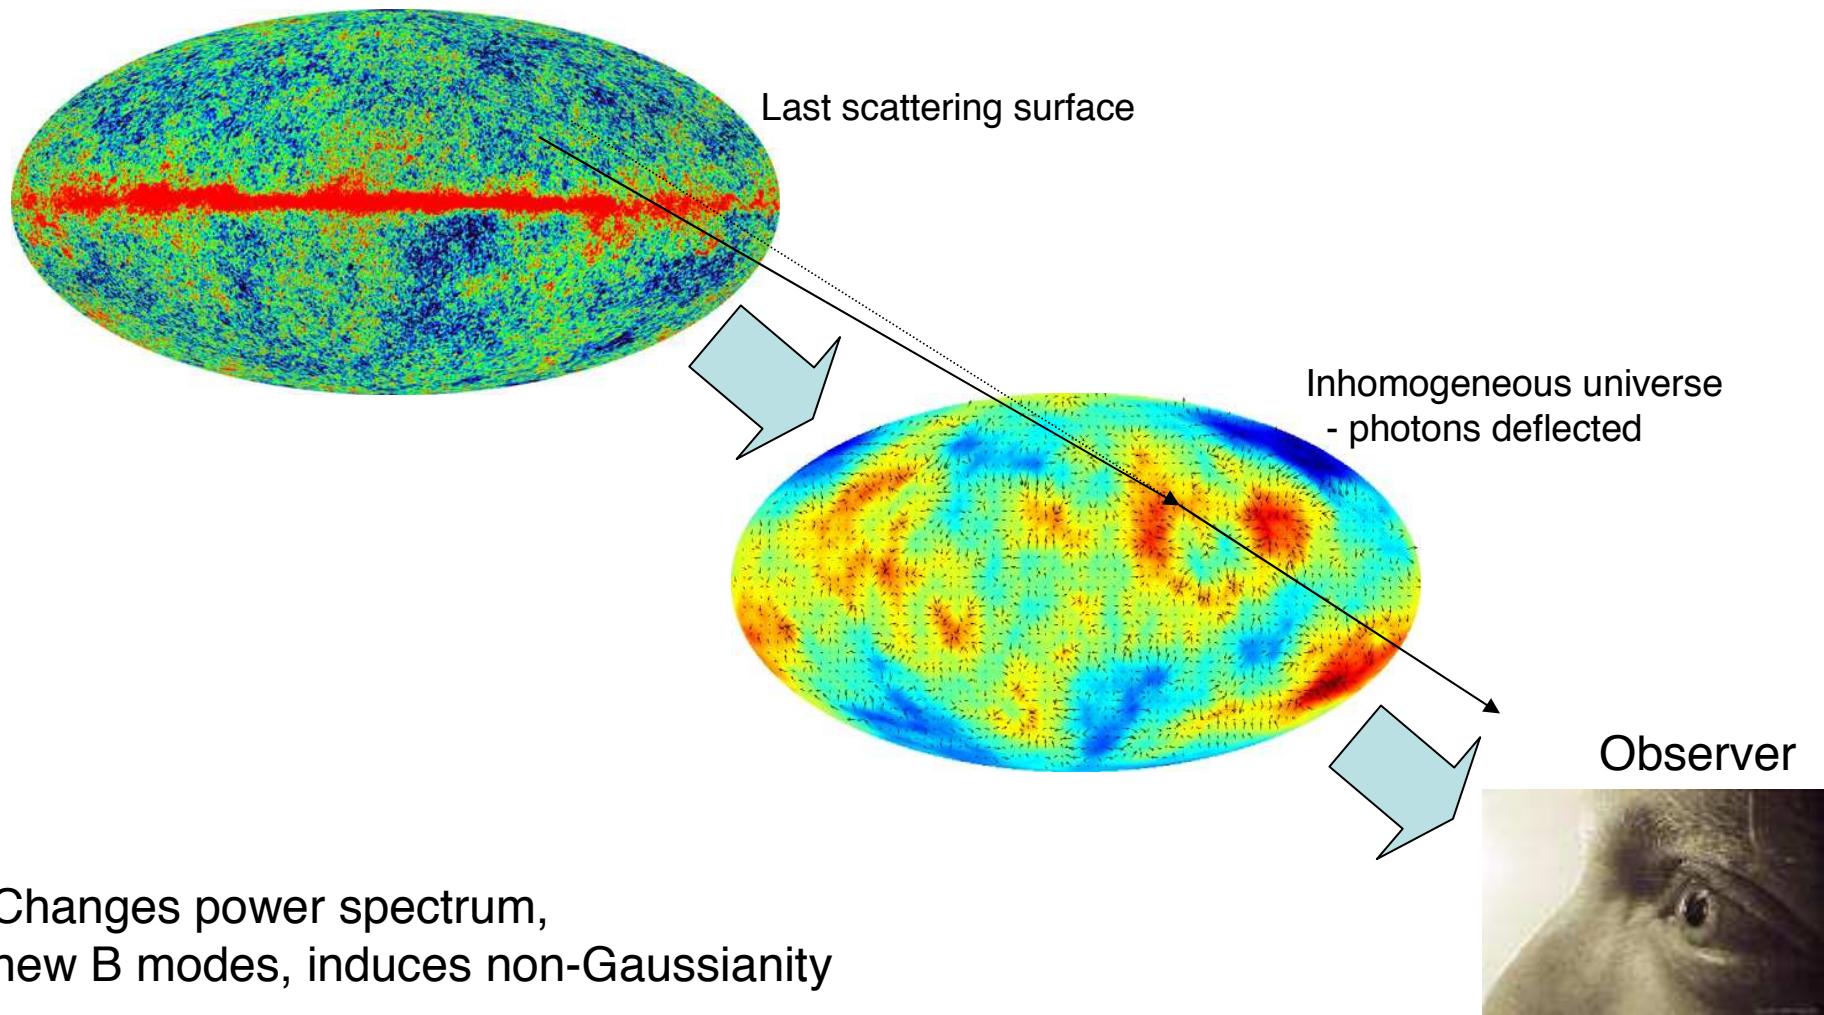

$r \sim 0.1$  in 14 months

$r \sim 0.05$  if 28 months ([Efstathiou, Gratton 09](#))

If it can be done for B-modes, E-mode reionization should also be OK

# Beyond linear order

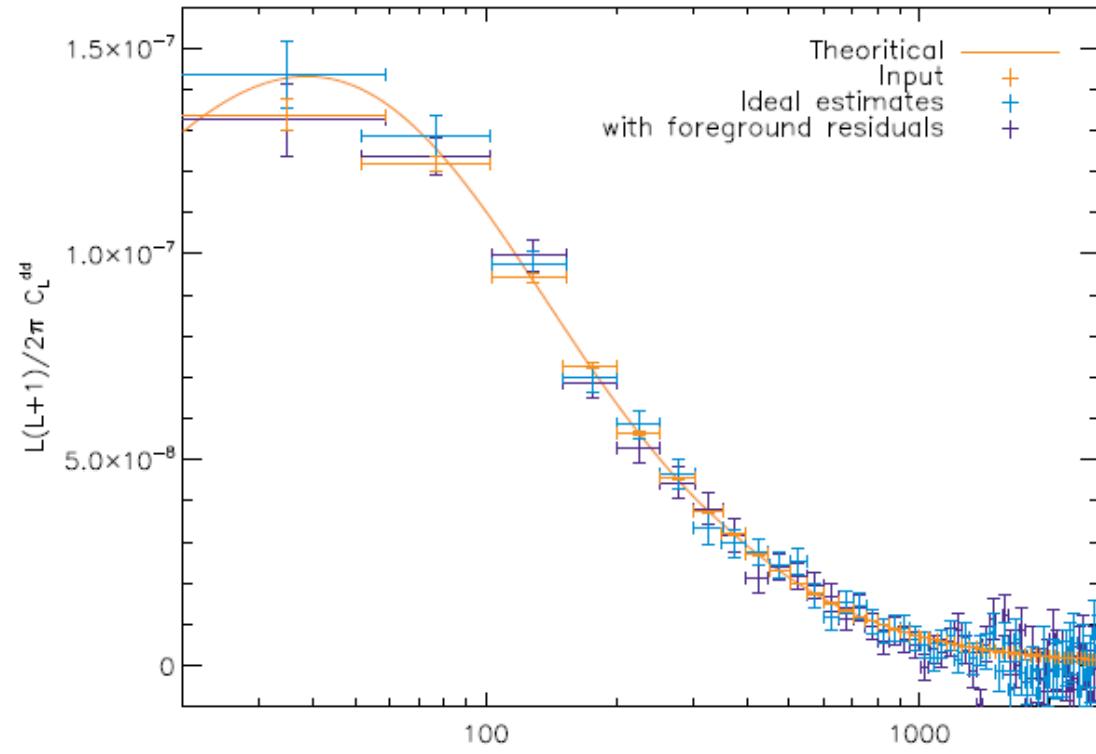

Weak lensing to break CMB degeneracies

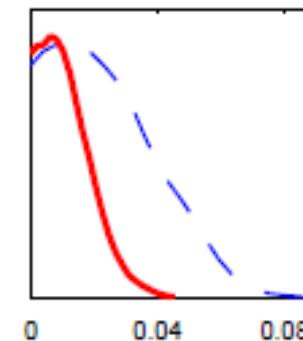

Review: Lewis & Challinor *Phys. Rept.* 429, 1-65 (2006): astro-ph/0601594

Probe  $0.5 < z < 6$ : depends on geometry and matter power spectrum

Already helps with Planck

Neutrino mass fraction  
with and without  
lensing (Planck only)

Also kSZ<sup>2</sup> x Lensing signal (Dore et al. 2004)

# Conclusions

- Looking good!
- Precision cosmology parameters
- Maybe B-mode from gravitational wave temperature quadrupole scattering at reionization
- Good constraint on optical depth
- Physical reionization models useful for extracting other parameters
- See Blue Book for other areas of science case
- Next talks for SZ/kSZ/reionization reconstruction...
