

# Update of Standard Model Higgs searches in ATLAS

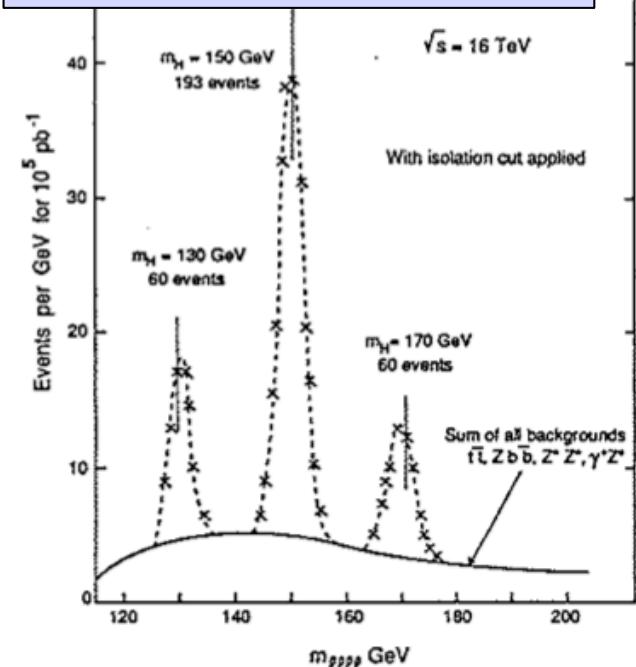

Fabiola Gianotti,  
representing the  
ATLAS Collaboration

Higgs searches have guided the conception, design and technological choices of ATLAS and CMS:

- perhaps the primary LHC goal
- among the most challenging processes  
→ have set some of the most stringent performance (hence technical) requirements: lepton identification, lepton energy/momentum resolution, b-tagging,  $E_T^{\text{miss}}$  measurement, forward-jet tagging, etc.

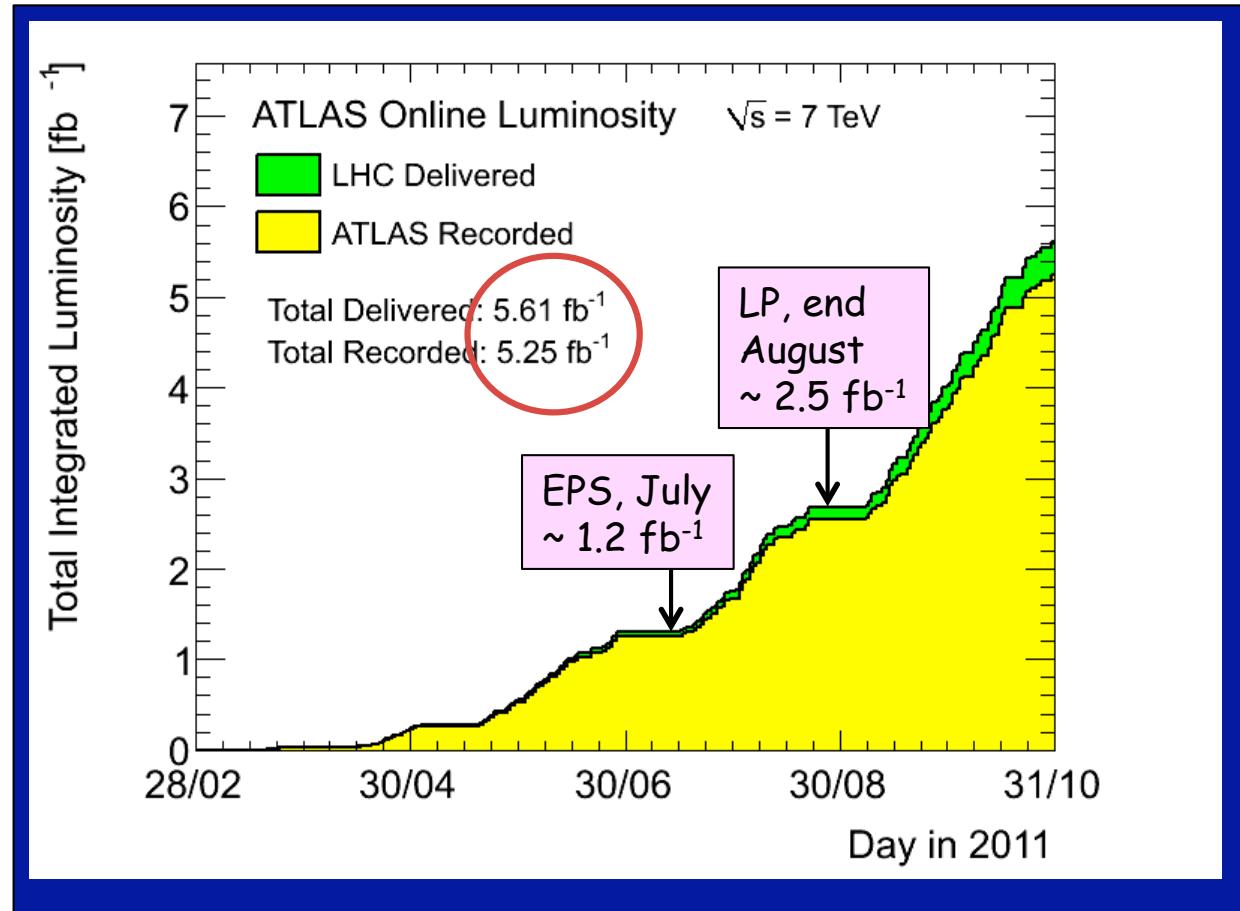

Proceedings of LHC Workshop (Aachen, 1990):  $H \rightarrow 4l$  signals  
 $m_H = 130, 150, 170 \text{ GeV}$   
 $\sqrt{s} = 16 \text{ TeV}, 100 \text{ fb}^{-1}$

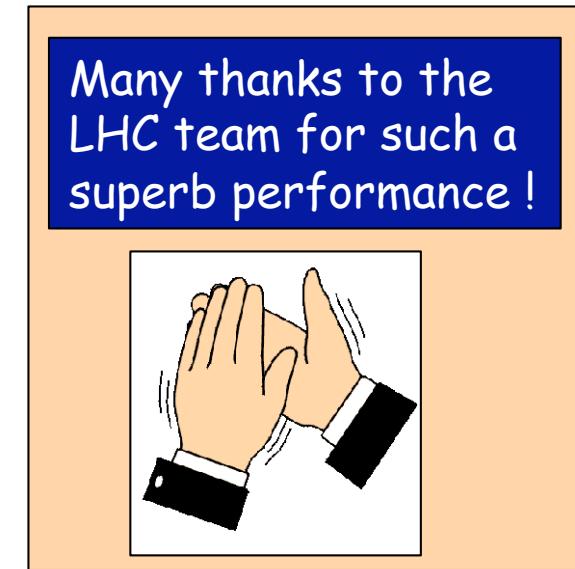

After 2 years of LHC operation, ATLAS has achieved excellent sensitivity over a large part of the allowed mass range, thanks to:

- outstanding LHC performance →  $> 5 \text{ fb}^{-1}$
- high detector operational efficiency and data quality
- excellent detector performance; mature understanding reflected in detailed modeling of several subtle effects included in the simulation
- huge numbers of physics results produced with the 2010-2011 data → the main SM processes and many backgrounds to Higgs searches studied in detail (and compared to theory)

→ Work of building solid foundations for (difficult) Higgs searches is well advanced

Peak luminosity seen by ATLAS:  
 $\sim 3.6 \times 10^{33} \text{ cm}^{-2} \text{ s}^{-1}$

Fraction of non-operational detector channels:  
(depends on the sub-detector)

few permil to 3.5%

Data-taking efficiency = (recorded lumi)/(delivered lumi):

$\sim 93.5\%$

Good-quality data fraction, used for analysis :  
(depends on the analysis)

90-96%

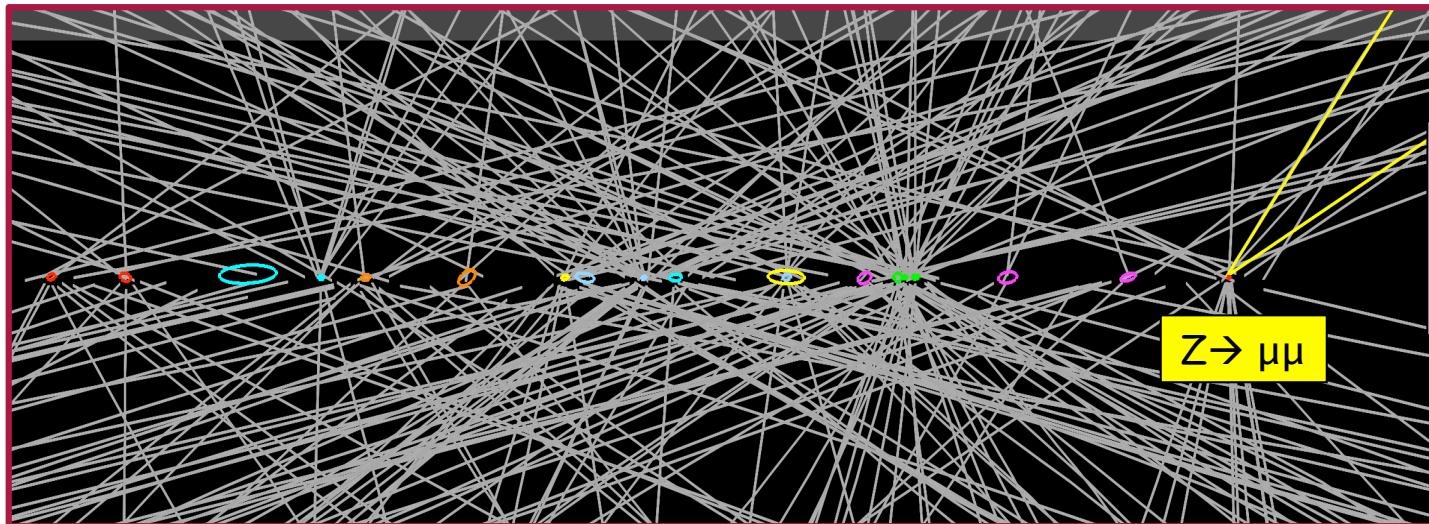

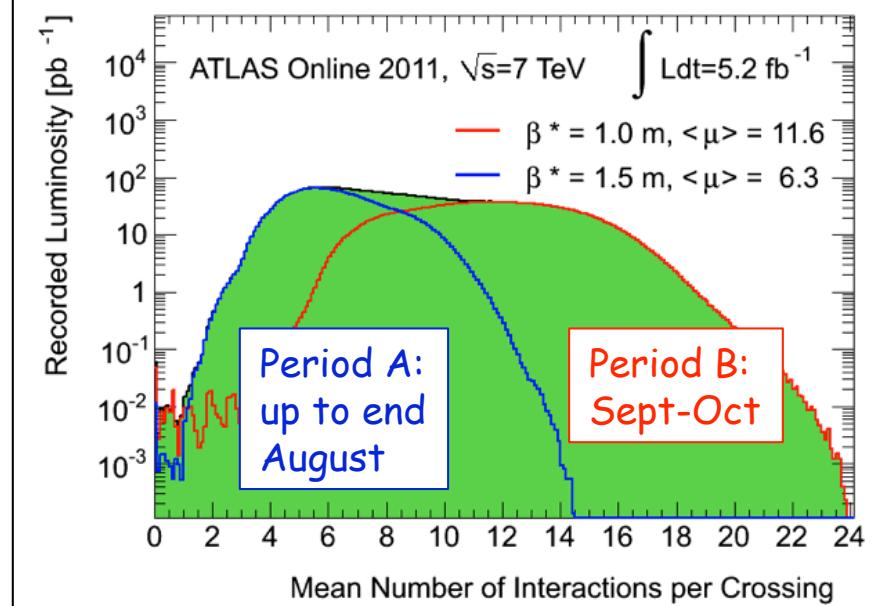

## Price to pay for the high luminosity: larger-than-expected pile-up

Pile-up = number of interactions per crossing

Tails up to  $\sim 20 \rightarrow$  comparable to design luminosity

(50 ns operation; several machine parameters pushed beyond design)

LHC figures used over the last 20 years:  
 $\sim 2$  (20) events/crossing at  $L=10^{33}$  ( $10^{34}$ )

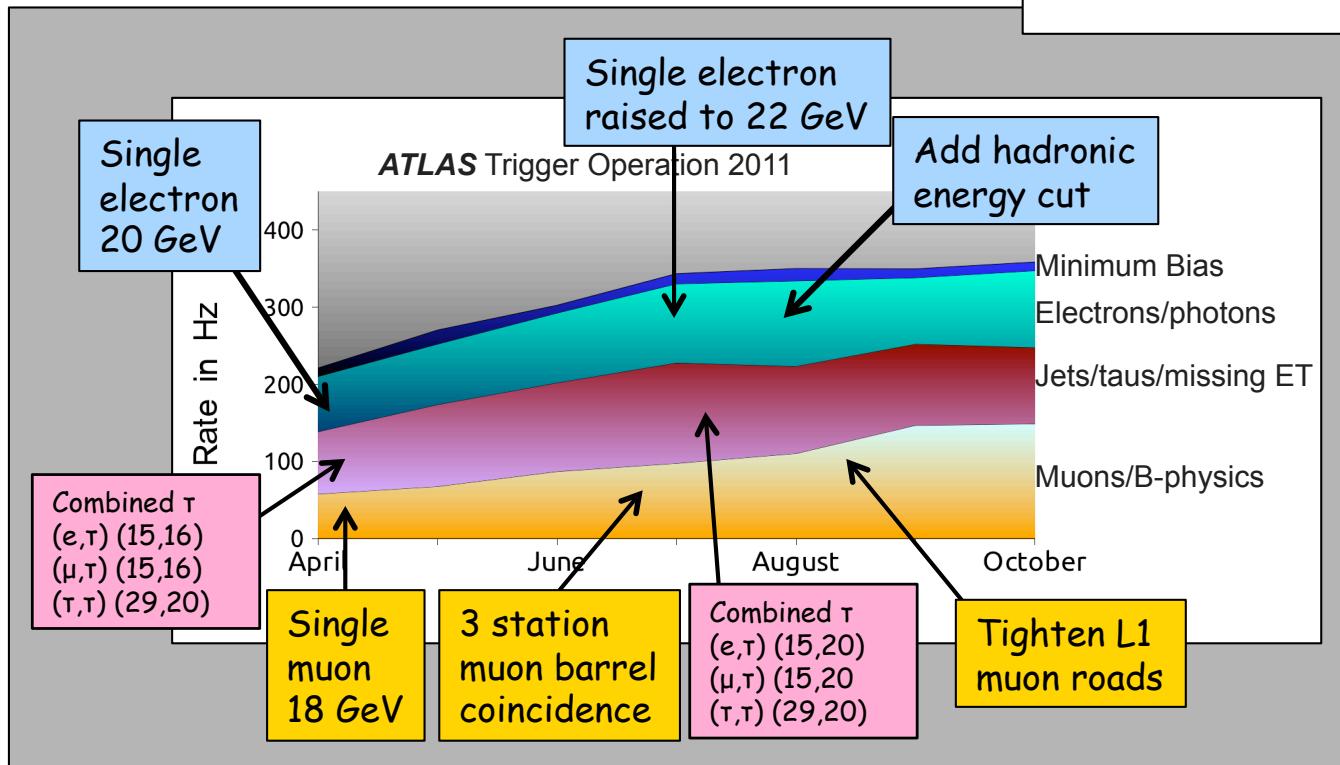

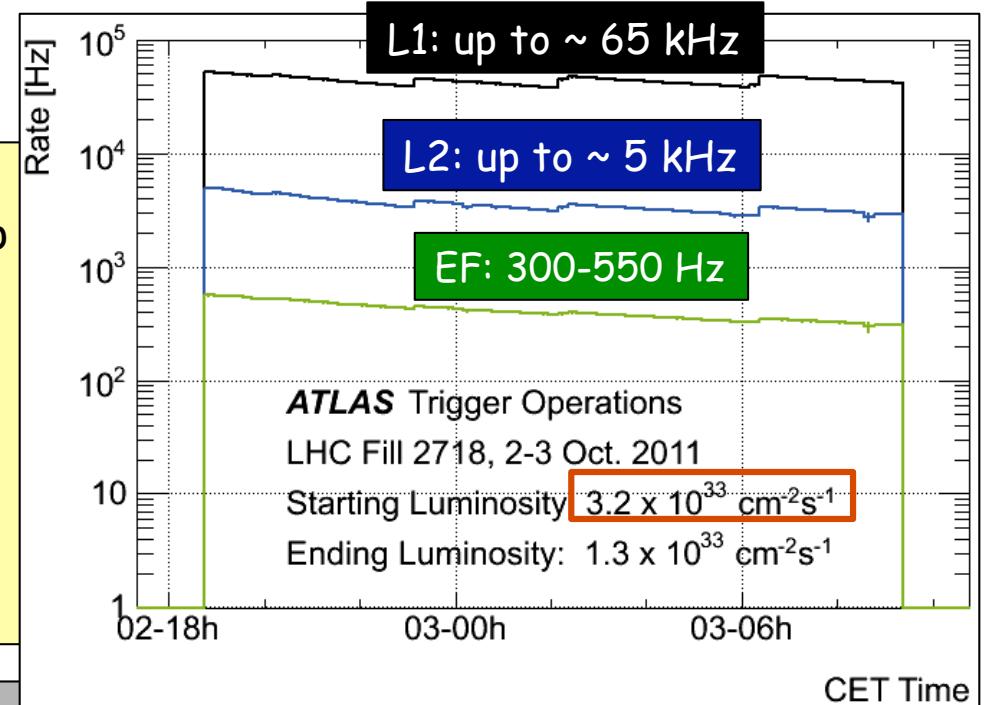

Challenging for trigger, computing resources, reconstruction of physics objects  
(in particular  $E_T^{\text{miss}}$ , soft jets, ..)

Precise modeling of both in-time and out-of-time pile-up in simulation is essential

# Trigger

- ❑ Coping very well with rapidly-increasing luminosity (factor ~10 over 2011) and pile-up by adapting prescales, thresholds, menu.
- ❑ Strive to maximise physics (e.g. keeping low thresholds for inclusive leptons)
- ❑ Main menu complemented by set of calibration/support triggers: e.g. special  $J/\psi \rightarrow ee$  stream (few Hz) for unbiased low- $p_T$  electron studies

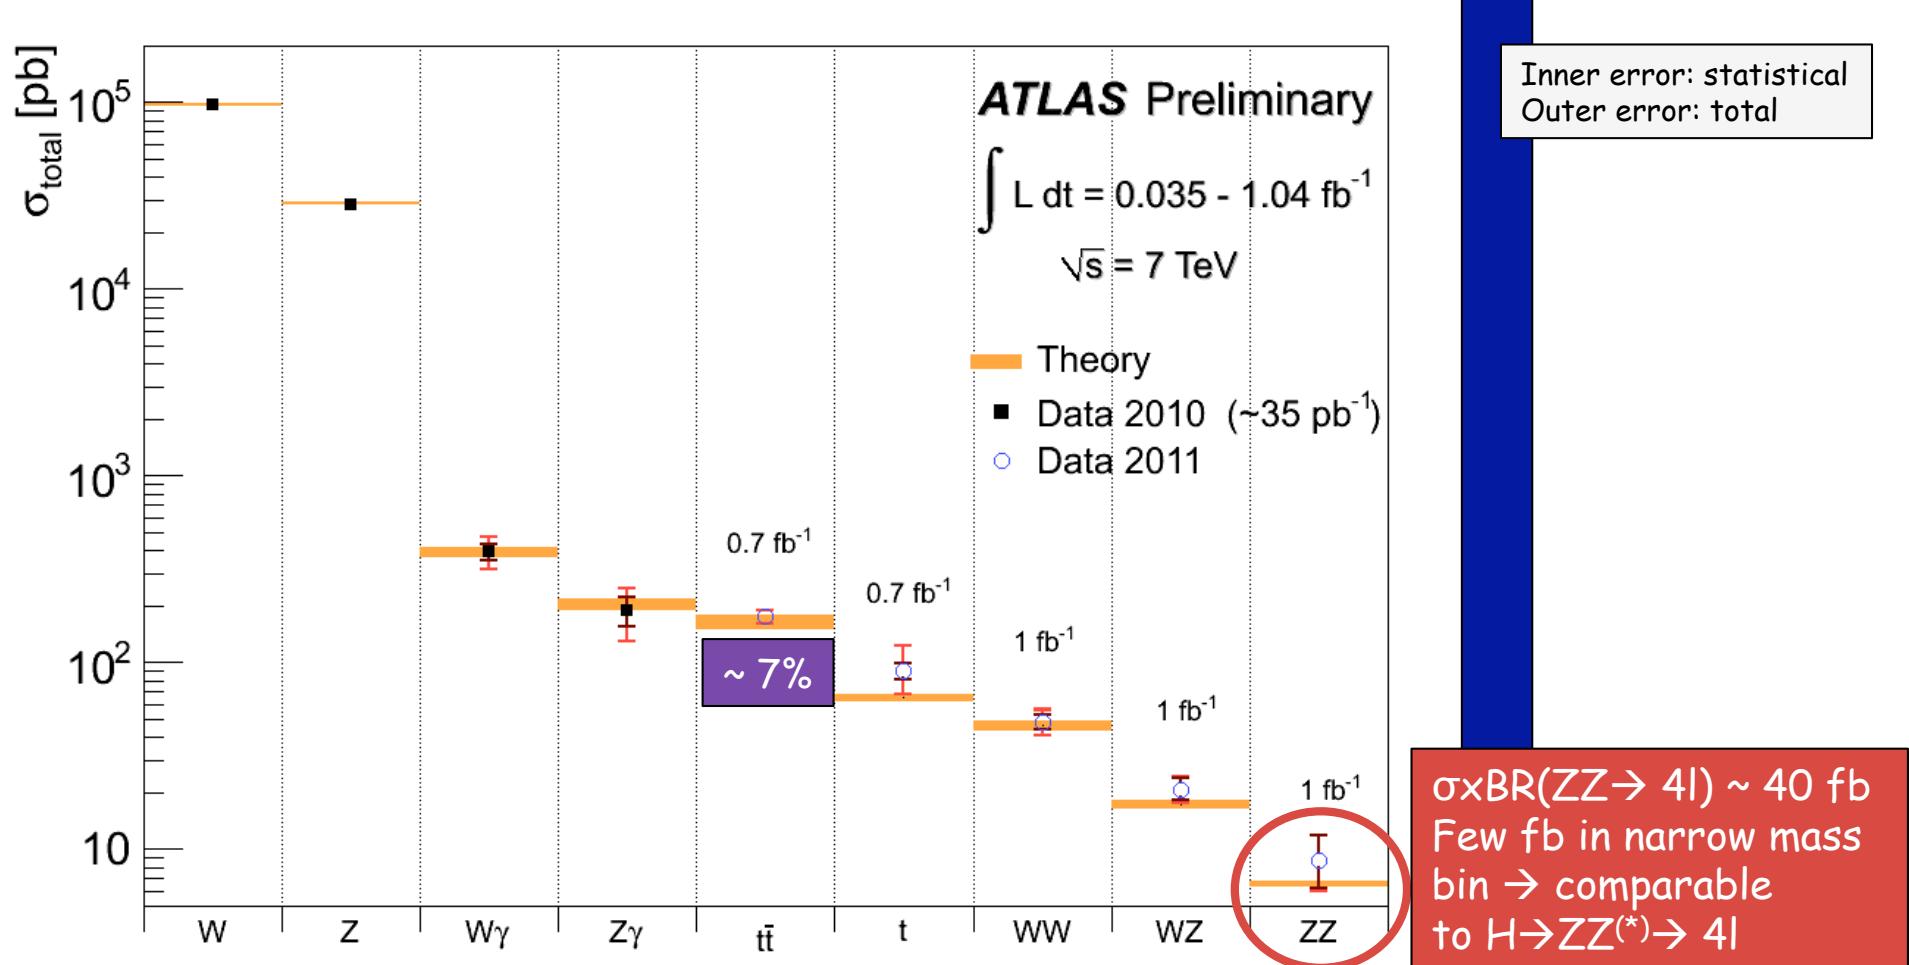

Typical recorded rates for main streams:

$e/\gamma$	$\sim 100 \text{ Hz}$
$\text{Jets}/\tau/E_T^{\text{miss}}$	$\sim 100 \text{ Hz}$
Muons	$\sim 150 \text{ Hz}$

Managed to keep inclusive lepton thresholds ~ stable during 2011

## Summary of main electroweak and top cross-section measurements

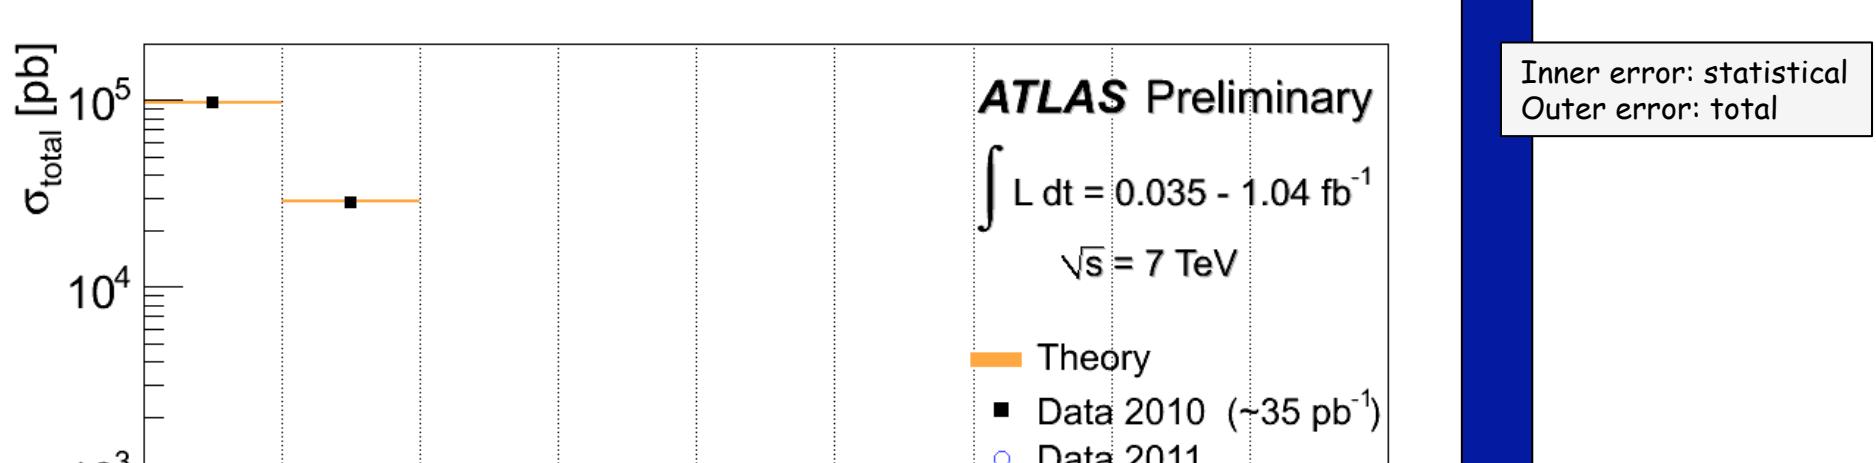

Good agreement with SM expectations (within present uncertainties)

Experimental precision starts to challenge theory for e.g.  $t\bar{t}$  (background to most H searches)

Measuring cross-sections down to few pb ( $\sim 40 \text{ fb}$  including leptonic branching ratios)

# Summary of main electroweak and top cross-section measurements

In our present dataset ( $\sim 5 \text{ fb}^{-1}$ ) we have (after selection cuts):

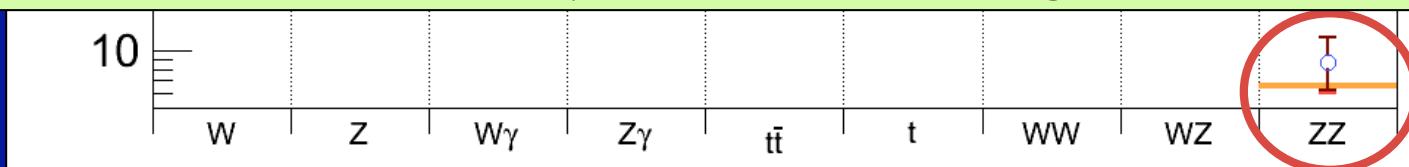

$\sim 30 \text{ M } W \rightarrow \mu\nu, e\nu$  events

$\sim 3 \text{ M } Z \rightarrow \mu\mu, ee$  events

$\sim 60000$  top-pair events

$\rightarrow$  factor  $\sim 2$  ( $W, Z$ ) to 10 (top) more than total CDF and D0 datasets

$\rightarrow$  will allow more and more precise studies of a larger number of (exclusive) processes

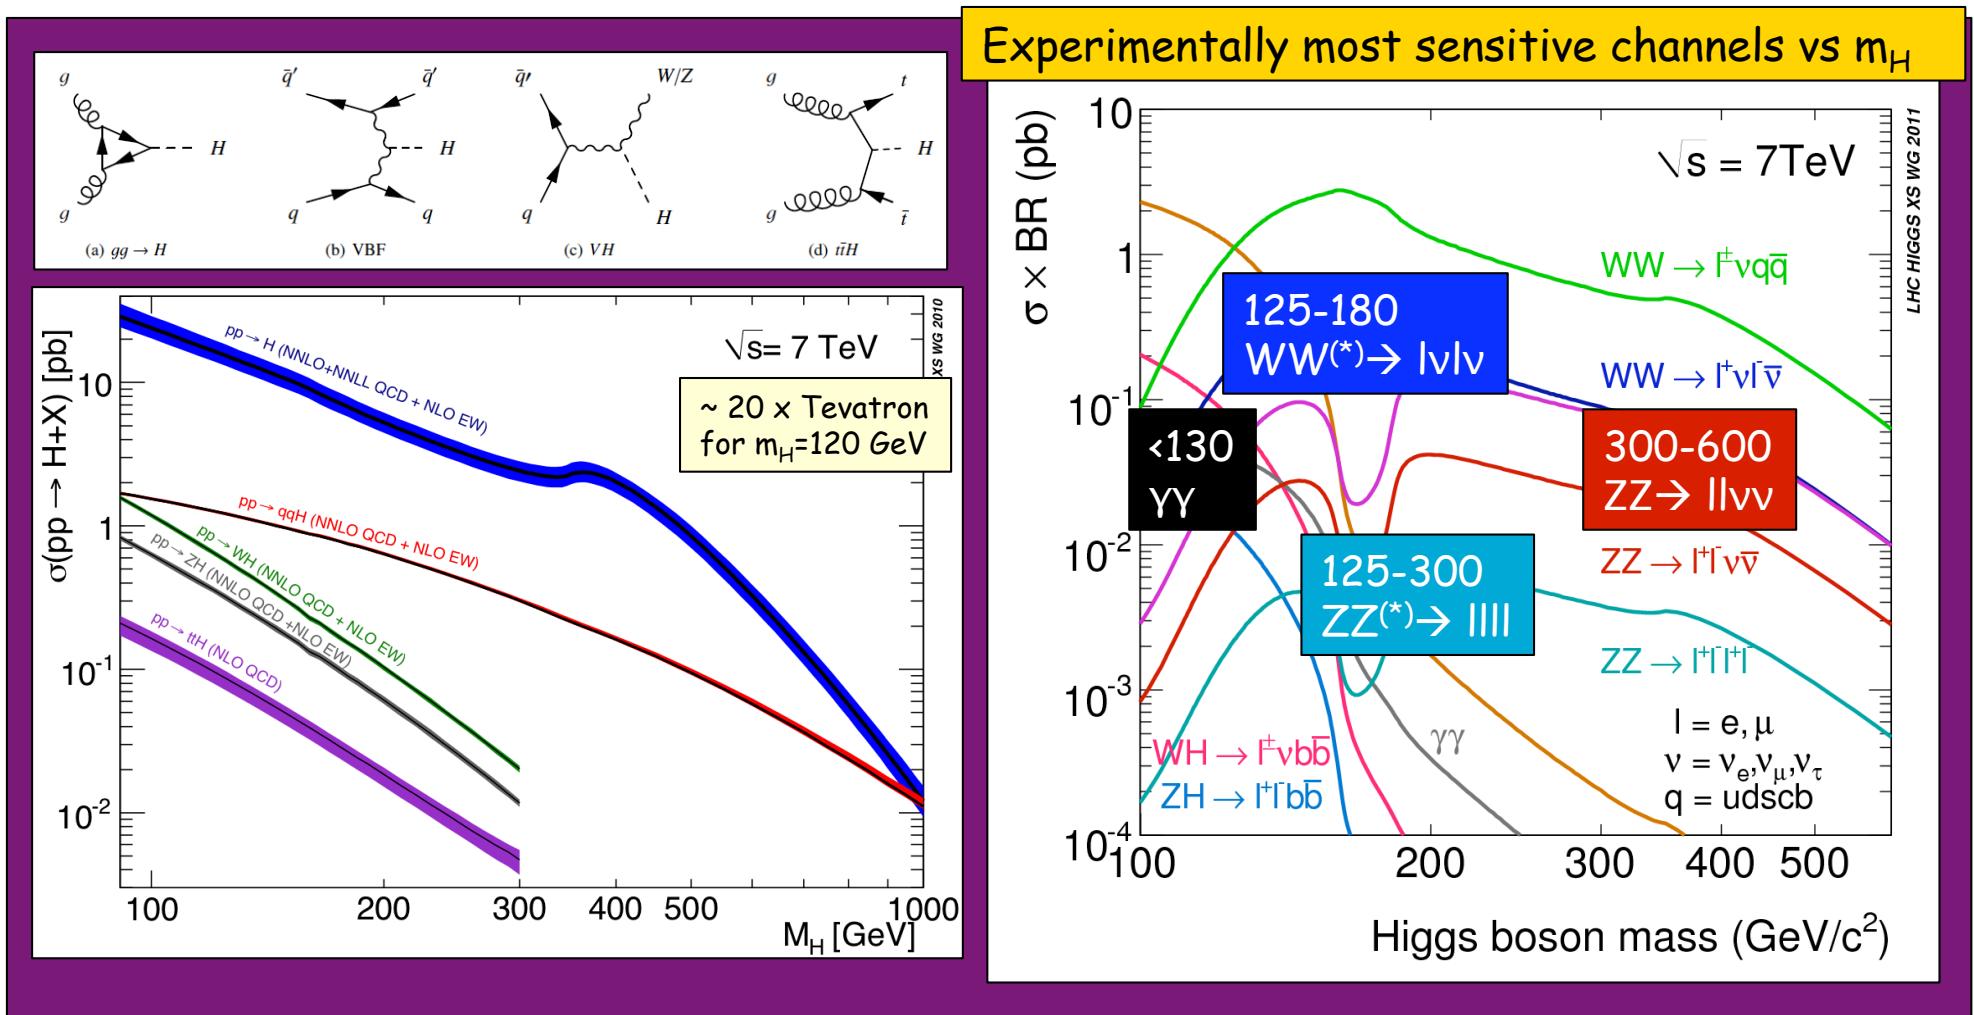

Few fb in narrow mass bin  $\rightarrow$  comparable to  $H \rightarrow ZZ^{(*)} \rightarrow 4l$

Good agreement with SM expectations (within present uncertainties)

Experimental precision starts to challenge theory for e.g.  $t\bar{t}$  (background to most  $H$  searches)

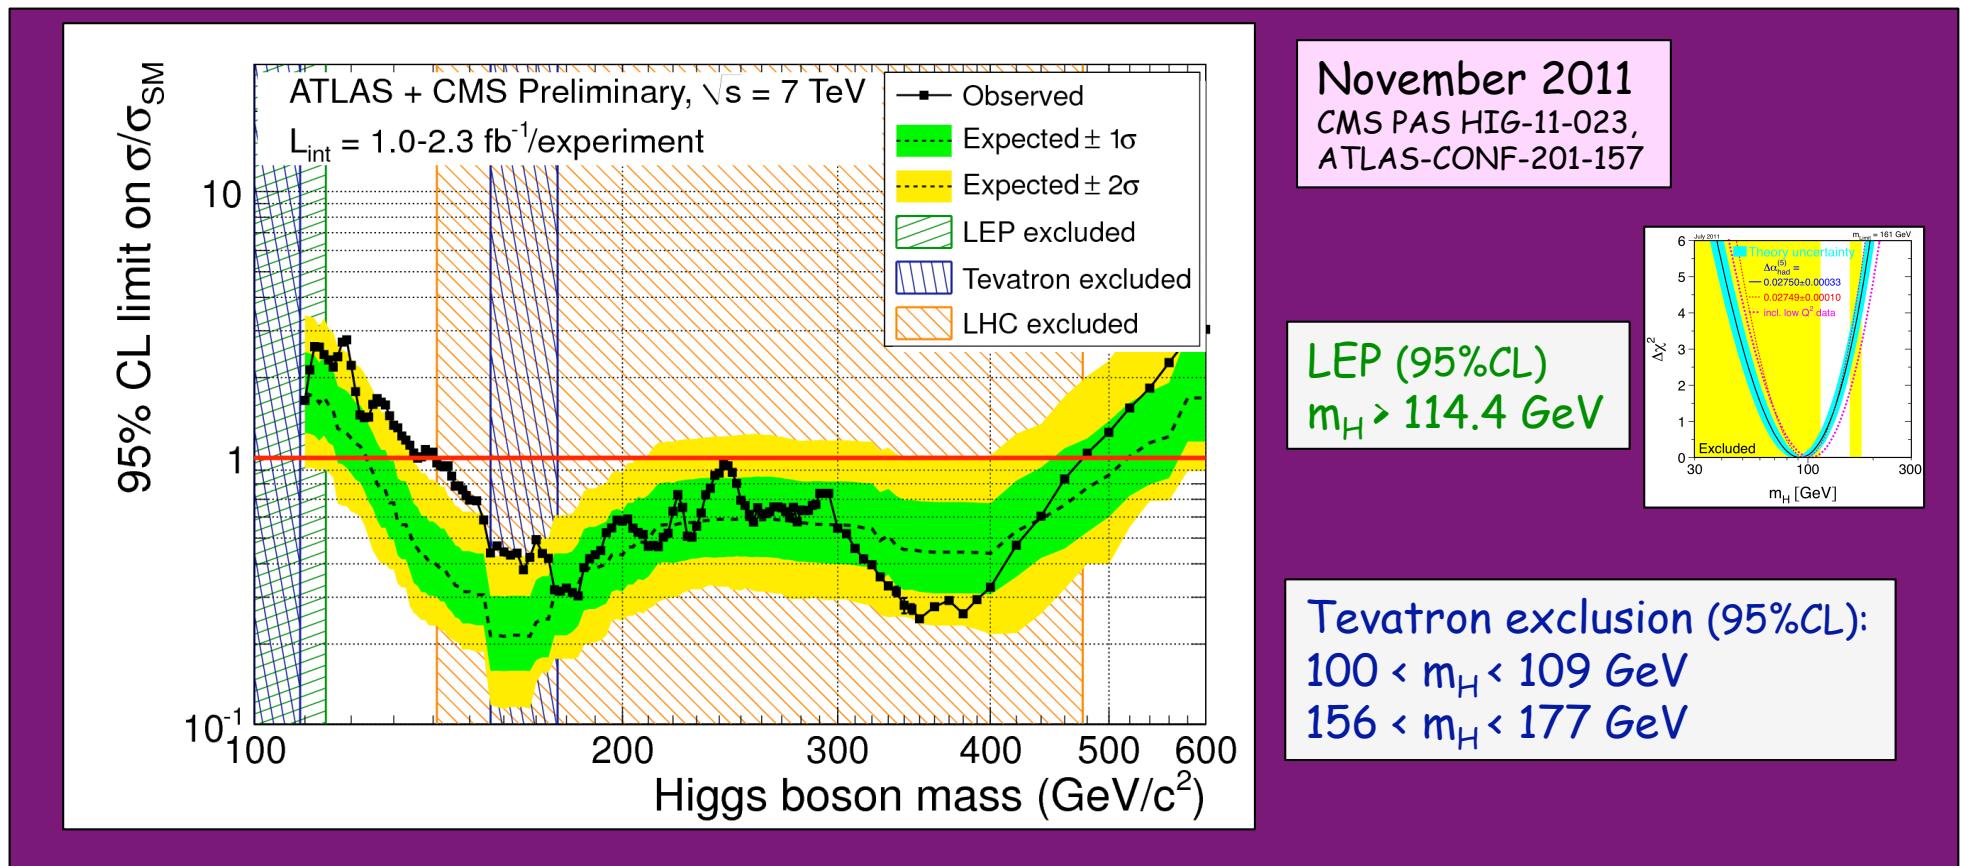

Measuring cross-sections down to few pb ( $\sim 40 \text{ fb}$  including leptonic branching ratios)

# SM Higgs production cross-section and decay modes

- Cross-sections computed to NNLO in most cases → theory uncertainties reduced to < 20%
- Huge progress also in the theoretical predictions of numerous and complex backgrounds  
→ Excellent achievements of the theory community; very fruitful discussions with the experiments (e.g. through LHC Higgs Cross Section WG, LPCC, etc.)

## Present status (as of this morning ...)

First ATLAS+CMS combination: based on data recorded until end August 2011:  
up to  $\sim 2.3 \text{ fb}^{-1}$  per experiment

Excluded 95% CL : 141-476 GeV  
Excluded 99% CL : 146-443 GeV (except  $\sim 222, 238-248, \sim 295 \text{ GeV}$ )  
Expected 95% CL : 124-520 GeV  $\rightarrow$  max deviation from background-only:  $\sim 3\sigma$  ( $m_H \sim 144 \text{ GeV}$ )

## Over the last months ...

Huge efforts to improve understanding of detector performance:

- 2011 data recorded with very different conditions compared to 2010, in particular the latest period with higher pile-up
  - several measurements with 2010 data already dominated by systematic uncertainty → need to dismantle systematics
- Improved knowledge (of many subtle effects...) propagated to simulation and reconstruction: detailed simulation of in- and out-of-time pile-up including bunch-train structure; new alignment; accurate simulation of absorber plates in the EM calorimeter (→ better agreement data-MC for e/γ showers); modeling varying detector conditions in MC; etc. etc.

Necessary, high-priority work for the full ATLAS physics programme based on the 2011 data

## Higgs searches:

We updated the most sensitive channels in the best motivated (EW fit) and not-yet-excluded low-mass region:  $H \rightarrow \gamma\gamma$  ( $4.9 \text{ fb}^{-1}$ ),  $H \rightarrow 4l$  ( $4.8 \text{ fb}^{-1}$ ),  $H \rightarrow WW \rightarrow llvv$  ( $2.1 \text{ fb}^{-1}$ )

## Micro-summary of present Higgs searches in ATLAS

Channel	$m_H$ range (GeV)	Int. lumi $\text{fb}^{-1}$	Main backgrounds	Number of signal events after cuts	S/B after cuts	Expected $\sigma/\sigma_{\text{SM}}$ sensitivity
$H \rightarrow \gamma\gamma$	110-150	4.9	$\gamma\gamma, \gamma j, jj$	~70	~0.02	1.6-2
$H \rightarrow \tau\tau \rightarrow ll + v$	110-140	1.1	$Z \rightarrow \tau\tau, \text{top}$	~0.8	~0.02	30-60
$H \rightarrow \tau\tau \rightarrow l\tau_{\text{had}}$	100-150	1.1	$Z \rightarrow \tau\tau$	~10	~5 $10^{-3}$	10-25
$W/ZH \rightarrow bbl(l)$	110-130	1.1	$W/Z + \text{jets}, \text{top}$	~6	~5 $10^{-3}$	15-25
$H \rightarrow WW^{(*)} \rightarrow llvv$	110-300	2.1	$WW, \text{top}, Z + \text{jet}$	~20 (130 GeV)	~0.3	0.3-8
$H \rightarrow ZZ^{(*)} \rightarrow 4l$	110-600	4.8	$ZZ^*, \text{top}, Zbb$	~2.5 (130 GeV)	~1.5	0.7-10
$H \rightarrow ZZ \rightarrow llvv$	200-600	2.1	$ZZ, \text{top}, Z + \text{jets}$	~20 (400 GeV)	~0.3	0.8-4
$H \rightarrow ZZ \rightarrow llqq$	200-600	2.1	$Z + \text{jets}, \text{top}$	2-20 (400 GeV)	0.05-0.5	2-6
$H \rightarrow WW \rightarrow lvqq$	240-600	1.1	$W + \text{jets}, \text{top}, \text{jets}$	~45 (400 GeV)	$10^{-3}$	5-10

- Based on (conservative) cut-based selections
- Large and sometimes not well-known backgrounds estimated mostly with data-driven techniques using signal-free control regions

- Most sensitive channel over  $\sim 125\text{-}180 \text{ GeV}$  ( $\sigma \sim 200 \text{ fb}$ )
- However: challenging:  $2\nu \rightarrow$  no mass reconstruction/peak  $\rightarrow$  "counting channel"
- 2 isolated opposite-sign leptons, large  $E_T^{\text{miss}}$
- Main backgrounds: WW, top, Z+jets, W+jets  
 $\rightarrow m_{\parallel} \neq m_Z$ , b-jet veto, ...  
 $\rightarrow$  Topological cuts against "irreducible" WW background:  
 $p_{T\parallel}, m_{\parallel}, \Delta\phi_{\parallel}$  (smaller for scalar Higgs),  $m_T(\parallel, E_T^{\text{miss}})$

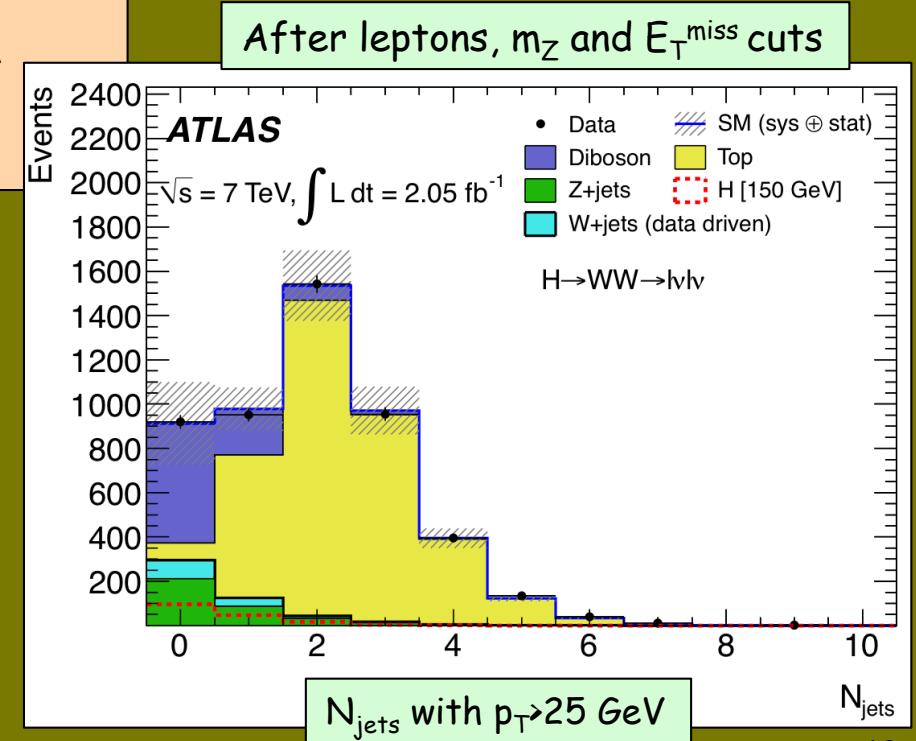

Crucial experimental aspects:

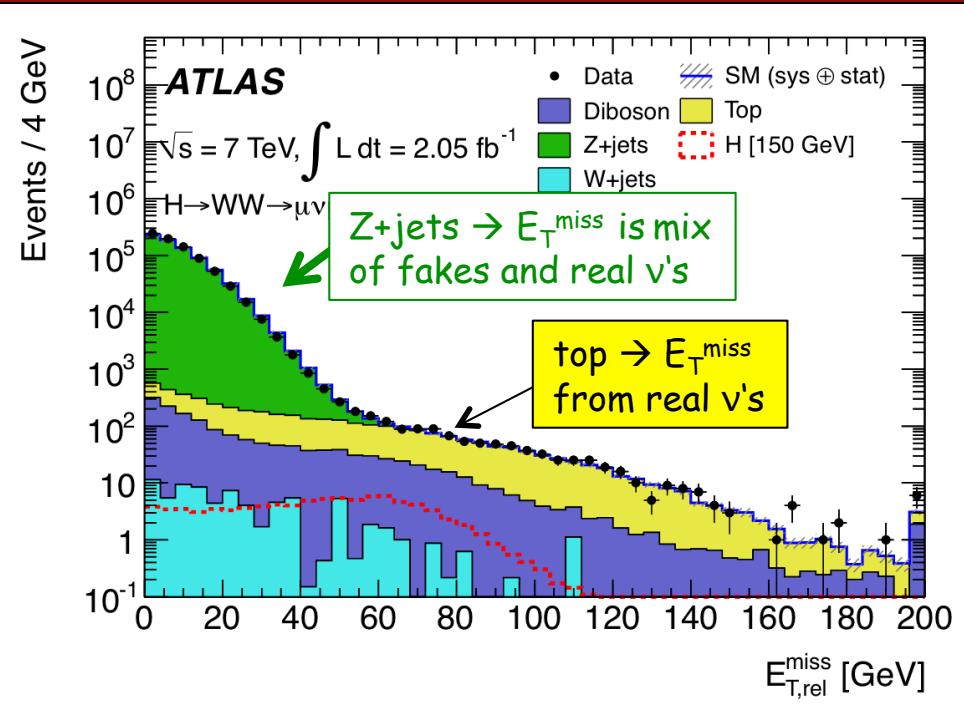

- understanding of  $E_T^{\text{miss}}$  (genuine and fake)
- excellent understanding of background in signal region  $\rightarrow$  use signal-free control regions in data to constrain MC  $\rightarrow$  use MC to extrapolate to the signal region

$2.1 \text{ fb}^{-1}$

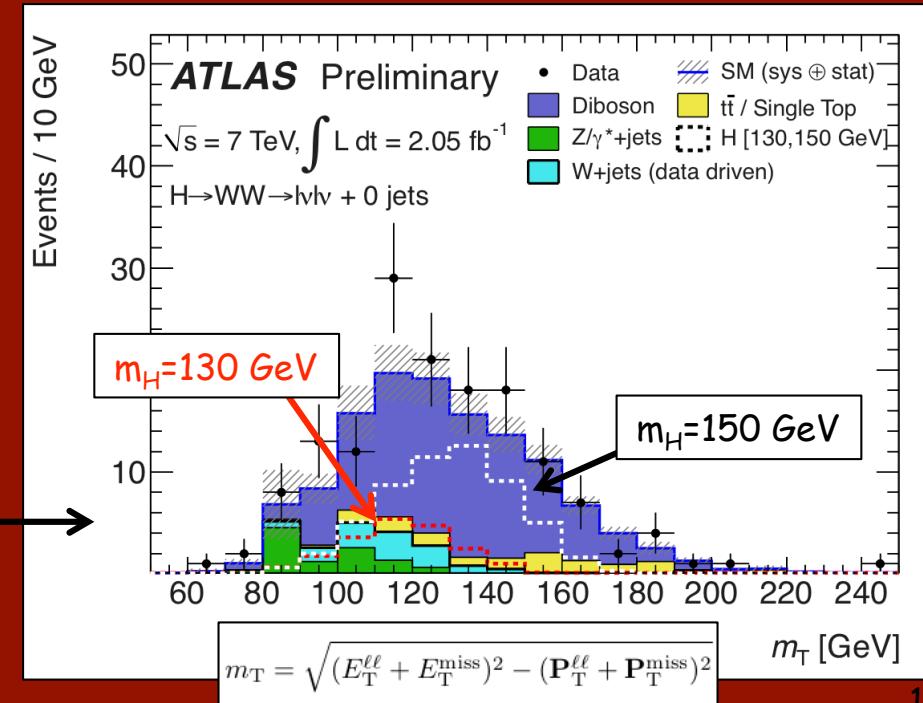

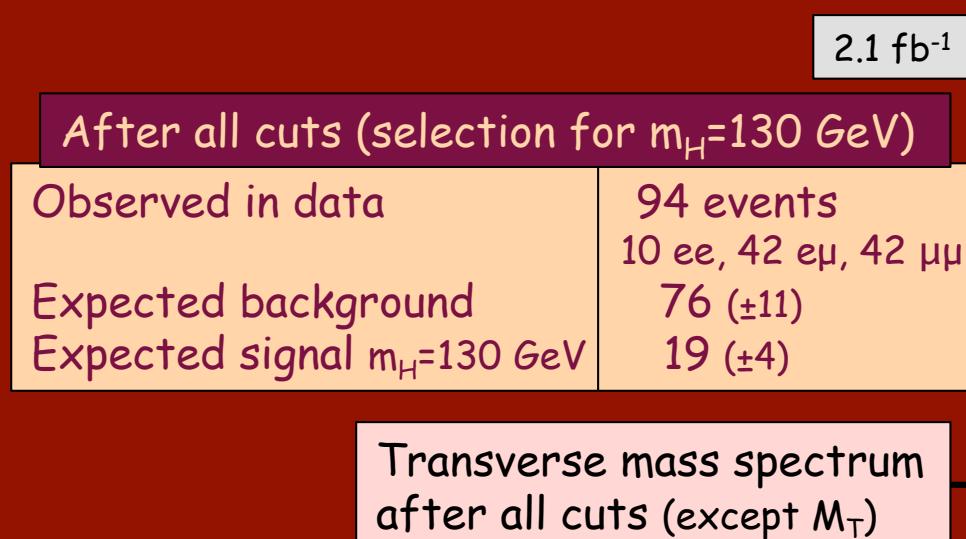

Control region	MC expectation	Observed in data
WW 0-jet	$296 \pm 36$	296
WW 1-jet	$171 \pm 21$	184
Top 1-jet	$270 \pm 69$	249

$E_T^{\text{miss}}$  spectrum in data for inclusive events with  $\mu^+\mu^-$  pair well described (over 5 orders of magnitude) by the various background components. Dominated by real  $E_T^{\text{miss}}$  from v's starting at  $E_T^{\text{miss}} \sim 50 \text{ GeV}$   $\rightarrow$  little tails from detector effects

$E_T^{\text{miss}}$  spectrum and resolution very sensitive to pile-up  $\rightarrow$  we will include Period-B data when understanding at similar level as Period A

After all cuts (selection for  $m_H=130$  GeV)

$2.1 \text{ fb}^{-1}$

Observed in data

94 events

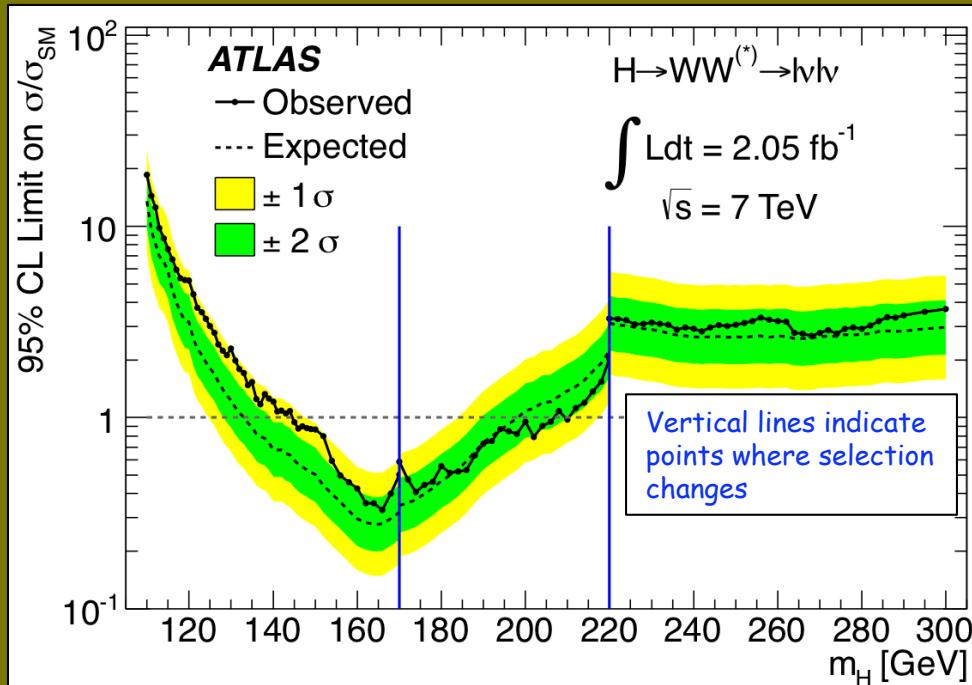

10 ee, 42 e $\mu$ , 42  $\mu\mu$

76 ( $\pm 11$ )

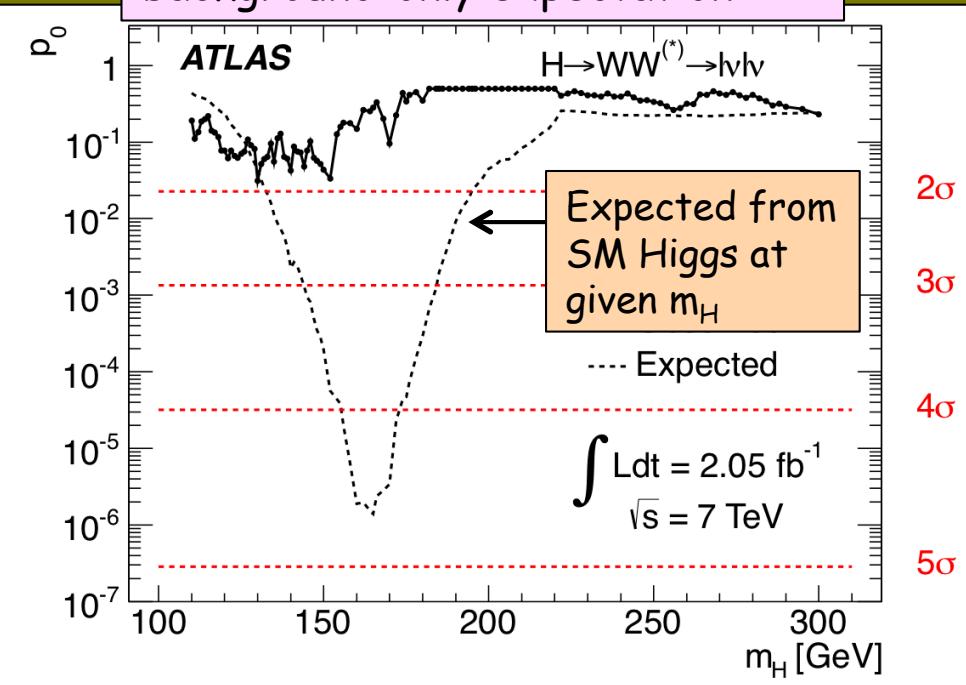

19 ( $\pm 4$ )

Expected background

Expected signal  $m_H=130$  GeV

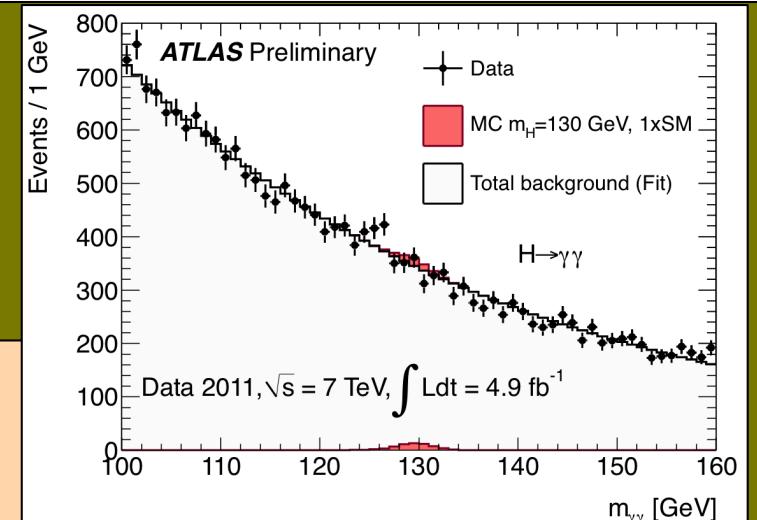

Consistency of the data with the background-only expectation

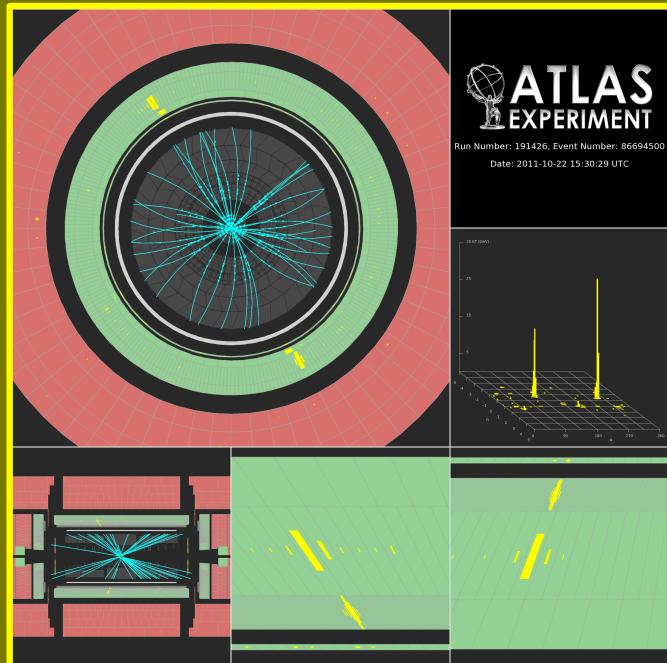

- Excluded (95% CL):  $145 < m_H < 206$  GeV (expected: 134-200 GeV)
- Observed limit within  $2\sigma$  of expected: max deviation  $1.9 \sigma$  for  $m_H \sim 130$  GeV

$H \rightarrow \gamma\gamma$

$110 \leq m_H \leq 150 \text{ GeV}$

- Small cross-section:  $\sigma \sim 40 \text{ fb}$
- Simple final state: two high- $p_T$  isolated photons  $E_T(\gamma_1, \gamma_2) > 40, 25 \text{ GeV}$
- Main background:  $\gamma\gamma$  continuum (irreducible, smooth, ...)
- Events divided into 9 categories based on  $\eta$ -photon (e.g. central, rest, ...), converted/unconverted,  $p_T^{\gamma\gamma}$  perpendicular to  $\gamma\gamma$  thrust axis
- $\sim 70$  signal events expected in  $4.9 \text{ fb}^{-1}$  after all selections for  $m_H = 125 \text{ GeV}$   
 $\sim 3000$  background events in signal mass window  $\rightarrow S/B \sim 0.02$

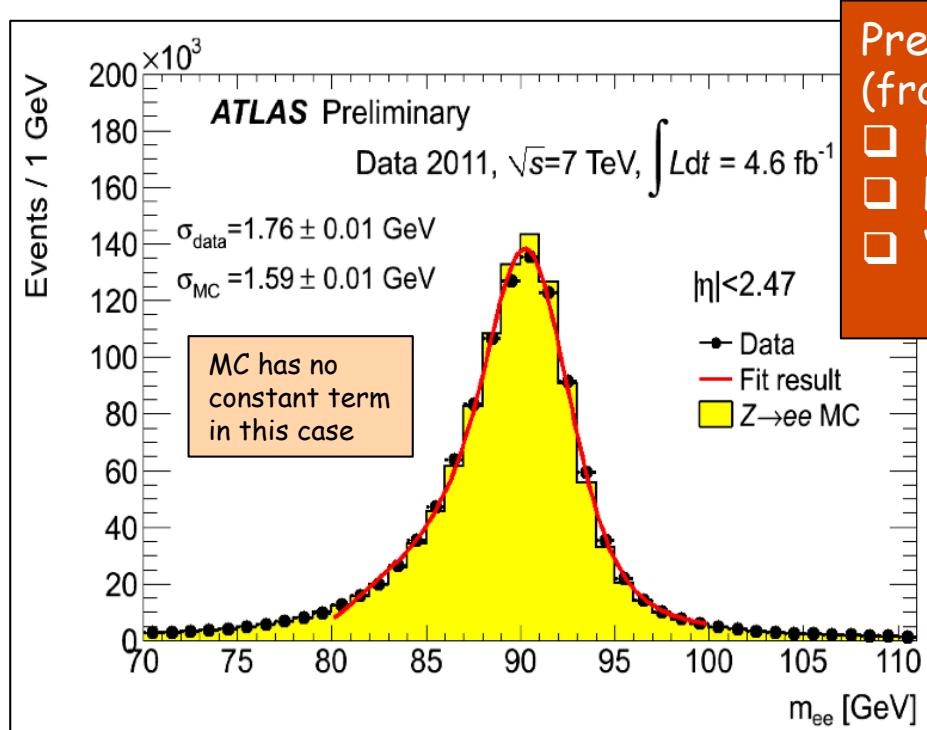

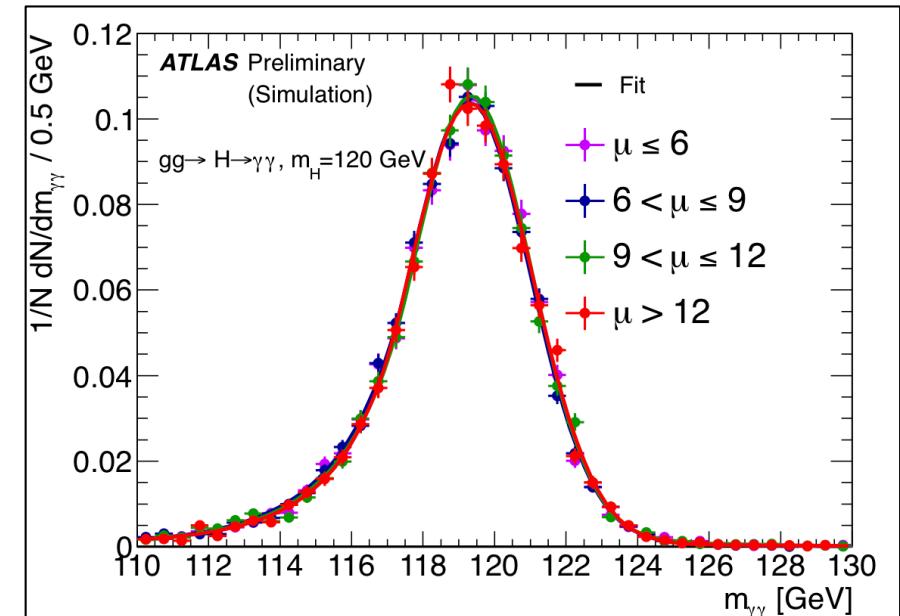

### Crucial experimental aspects:

- excellent  $\gamma\gamma$  mass resolution to observe narrow signal peak above irreducible background
- powerful  $\gamma$ /jet separation to suppress  $\gamma j$  and  $jj$  background with jet  $\rightarrow \pi^0$  faking single  $\gamma$

$$m_{\gamma\gamma}^2 = 2 E_1 E_2 (1 - \cos\alpha)$$

$m_H = 120 \text{ GeV}$	$\sigma(m_{\gamma\gamma}) \text{ GeV}$	Event fraction in $\pm 1.4 \sigma(m_{\gamma\gamma})$
All	1.7	80 %
Best category (unconverted central)	1.4	84%
Worst category (~10%) ( $\geq 1 \gamma$ converted, $\geq 1 \gamma$ near barrel/end-cap transition)	2.3	70%

Present understanding of calorimeter E response  
(from  $Z, J/\psi \rightarrow ee, W \rightarrow e\nu$  data and MC):

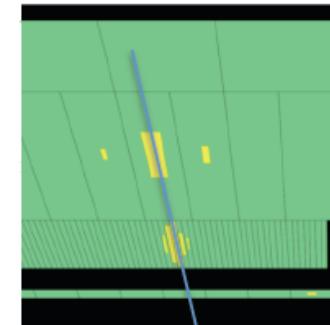

- Energy scale at  $m_Z$  known to  $\sim 0.5\%$
- Linearity better than 1% (over few GeV-few 100 GeV)
- “Uniformity” (constant term of resolution):  
1% (barrel) -1.7 % (end-cap)

Electron scale and resolution transported  
to photons using MC  
(systematics few from material effects)

$$m_{\gamma\gamma}^2 = 2 E_1 E_2 (1 - \cos\alpha)$$

$\alpha$ =opening angle of the two photons

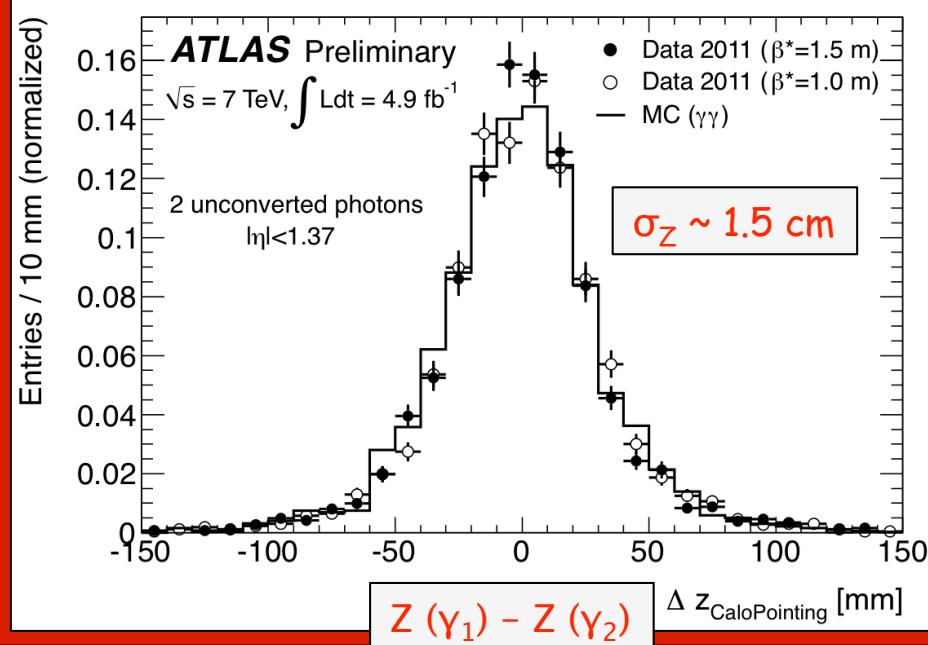

Use longitudinal (and lateral) segmentation of EM calorimeter to measure photon polar angle  $\theta$   
 crucial at high pile-up: many vertices distributed over  $\sigma_Z$  (LHC beam spot)  $\sim 5.6$  cm  $\rightarrow$  difficult  
 to know which one produced the  $\gamma\gamma$  pair

1.- Measure photon direction

2.- Deduce Z of primary vertex

Z-vertex as measured in  $\gamma\gamma$  events after selection from calorimeter "pointing"

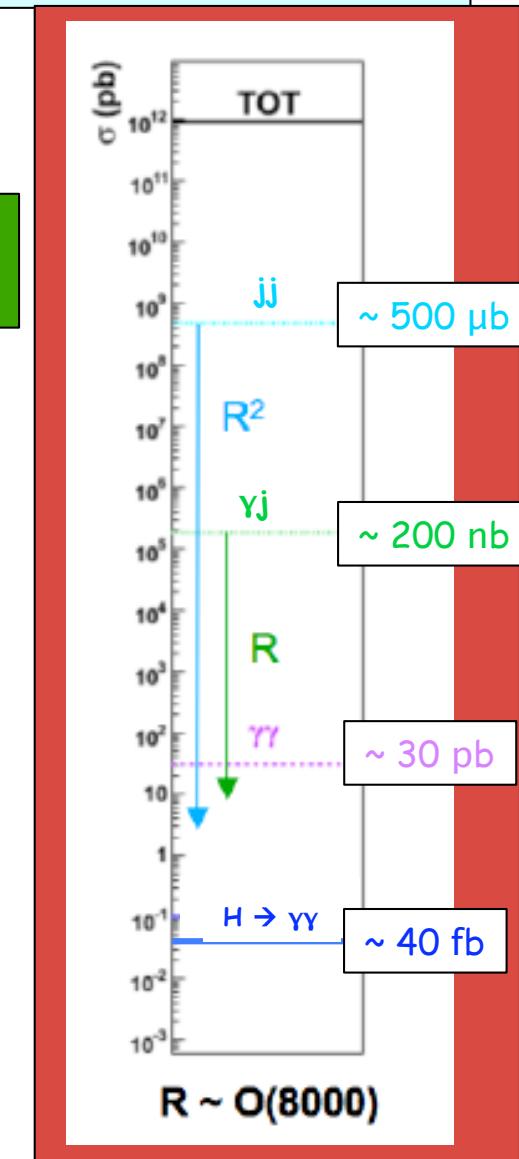

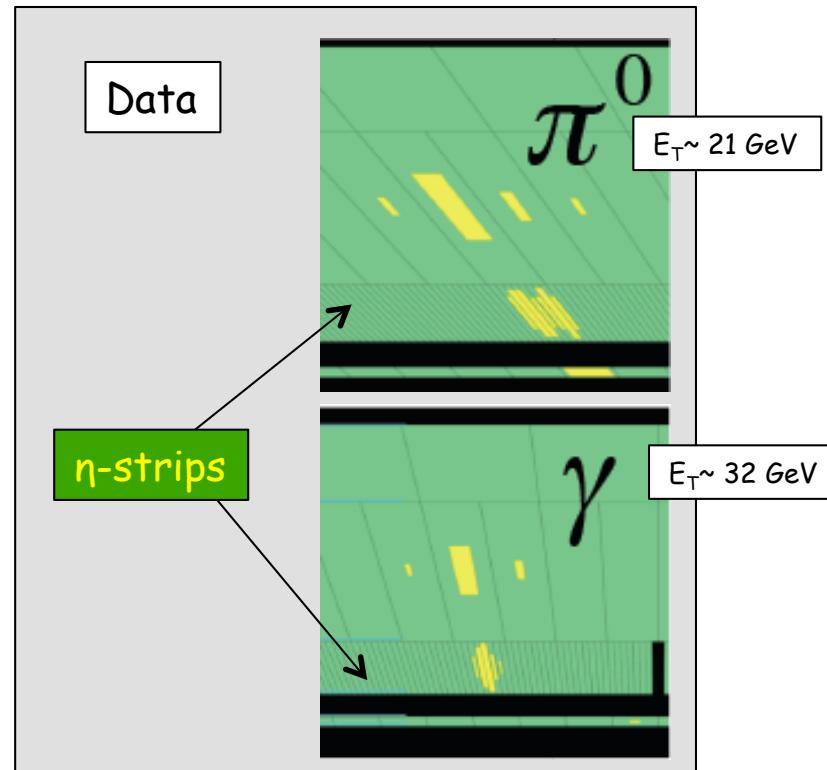

- Calorimeter pointing capability reduces vertex uncertainty from  $\sim 5.6$  cm (LHC beam spot) to  $\sim 1.5$  cm  
 $\rightarrow$  Contribution to mass resolution from angular term is negligible with calo pointing ( $\gamma \rightarrow ee$  vertex also used)
- Robust against pile-up

Potentially huge background from  $\gamma j$  and  $jj$  production with jets fragmenting into a single hard  $\pi^0$  and the  $\pi^0$  faking single photon

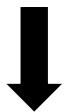

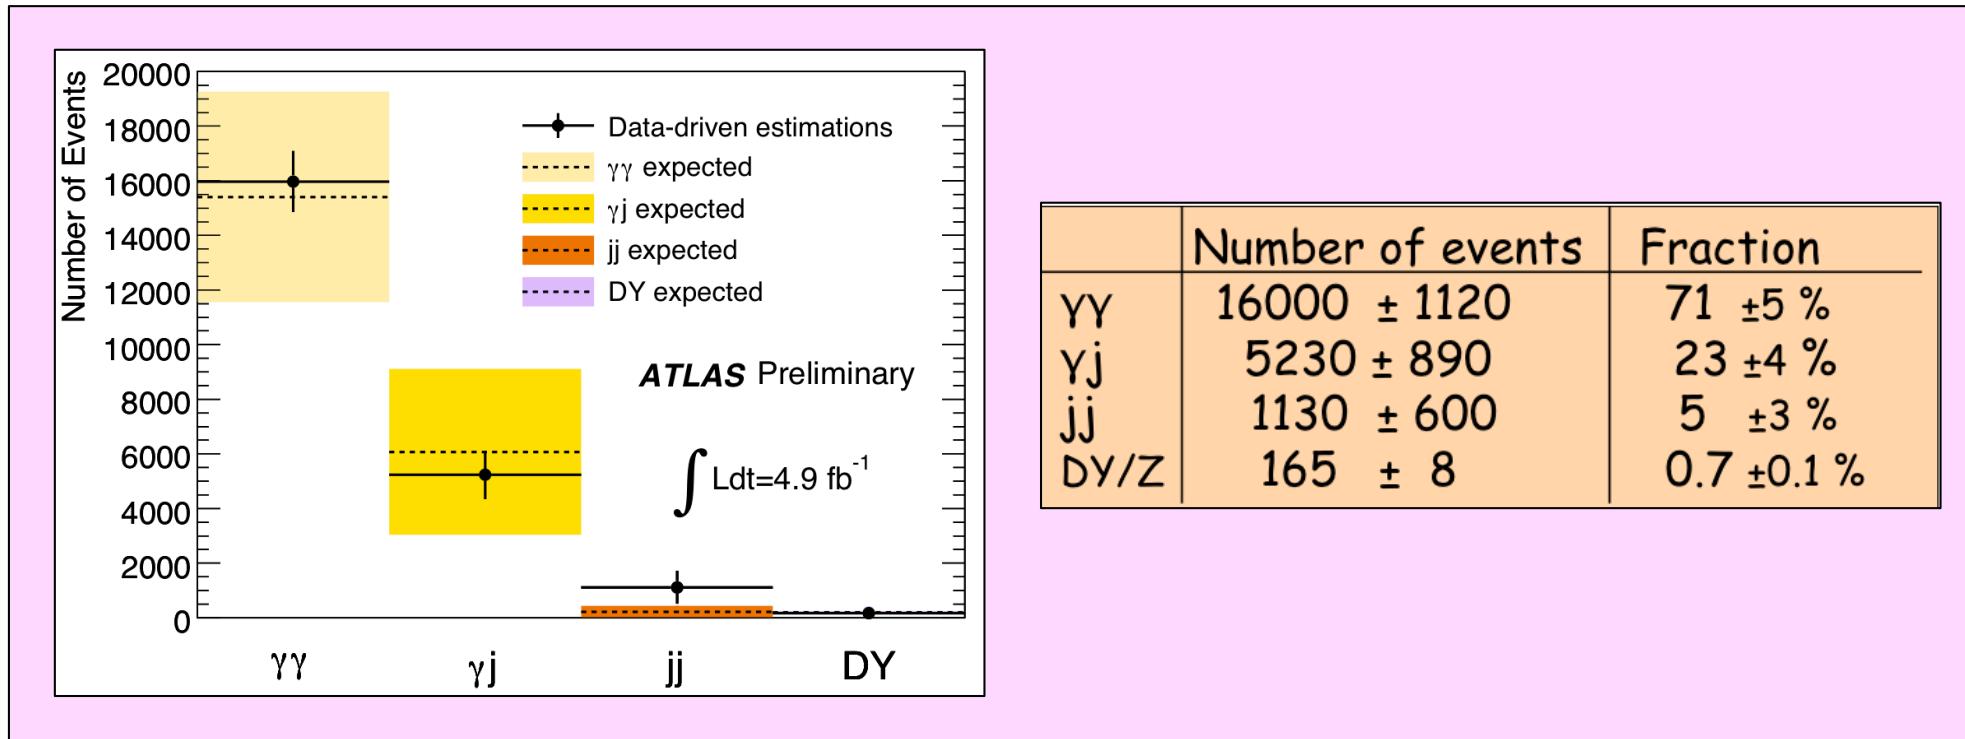

Determined choice of fine lateral segmentation (4mm  $\eta$ -strips) of the first compartment of ATLAS EM calorimeter

However: huge uncertainties on  $\sigma (\gamma j, jj)$  !!  $\rightarrow$  not obvious  $\gamma j, jj$  could be suppressed well below irreducible  $\gamma\gamma$  until we measured with data

After all cuts: 22489 events with  $100 < m_{\gamma\gamma} < 160$  GeV observed in the data

Sample composition estimated from data using control samples

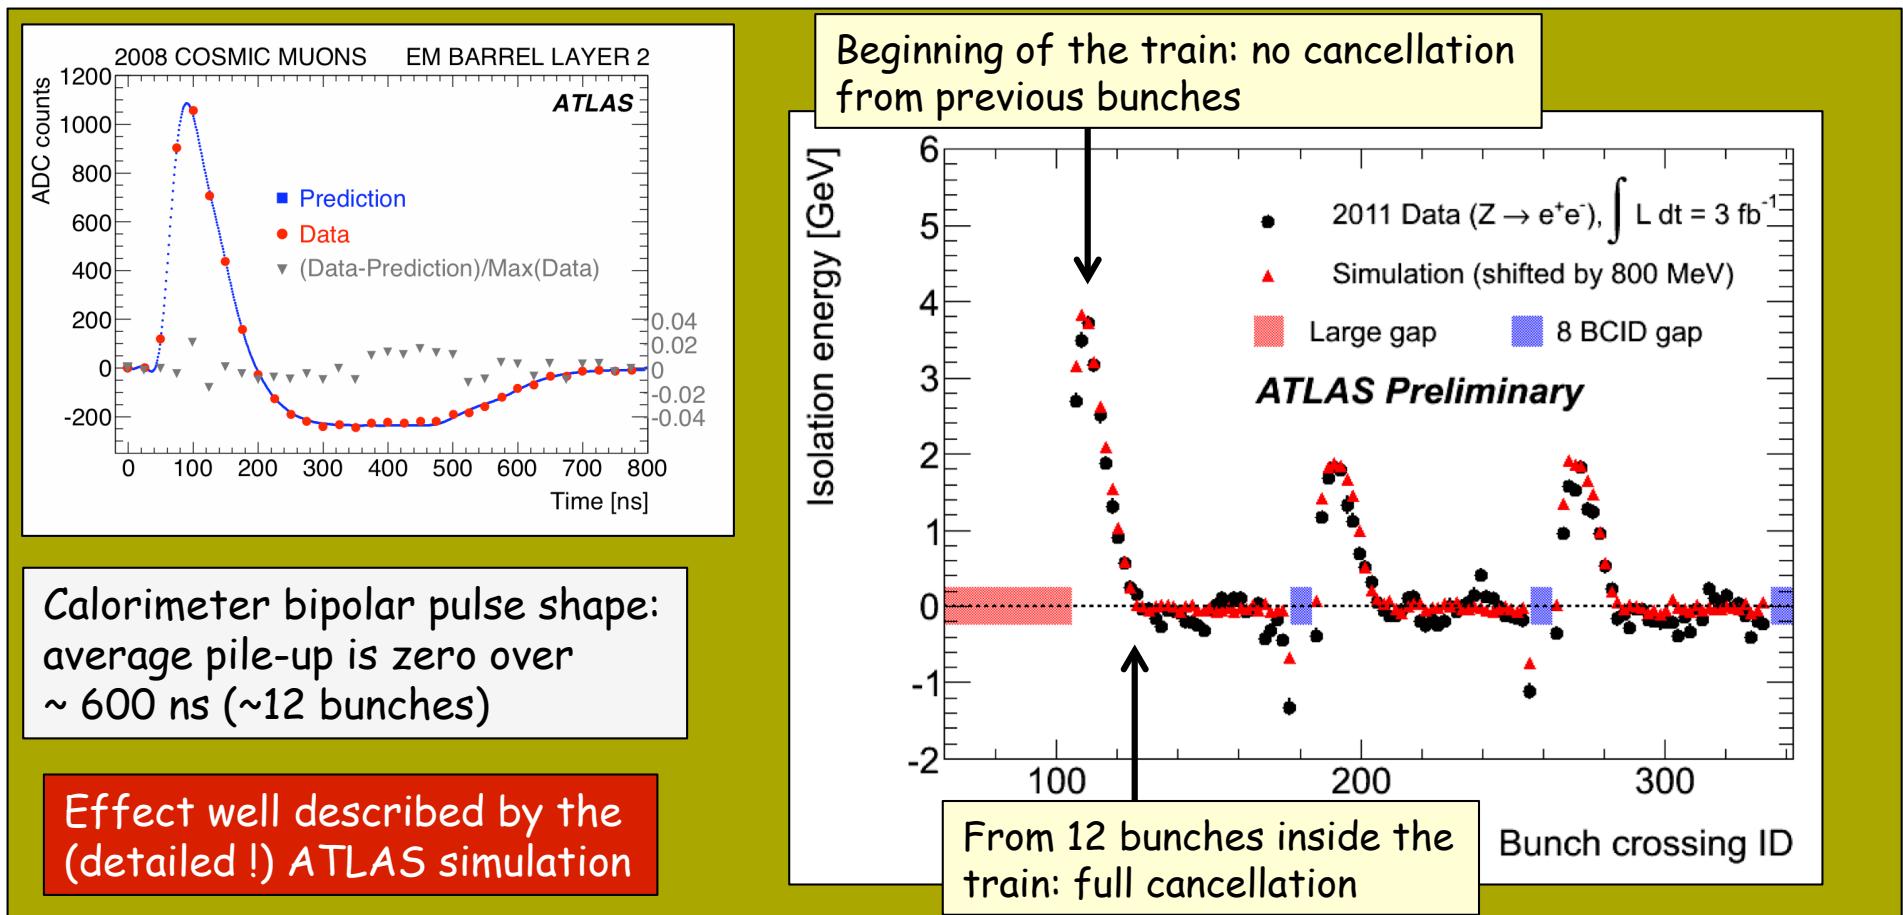

$\gamma j + jj \ll \gamma\gamma$  irreducible (purity  $\sim 70\%$ )

Photon identification efficiency:  $\sim 85 \pm 5\%$  from MC, cross-checked with data  
 $(Z \rightarrow ee, Z \rightarrow e\mu\gamma, \mu\mu\gamma)$

Photon identification efficiency:  $\sim 85\pm 5\%$  from MC, cross-checked with data ( $Z \rightarrow ee$ ,  $Z \rightarrow e\gamma\gamma$ ,  $\mu\mu\gamma$ )

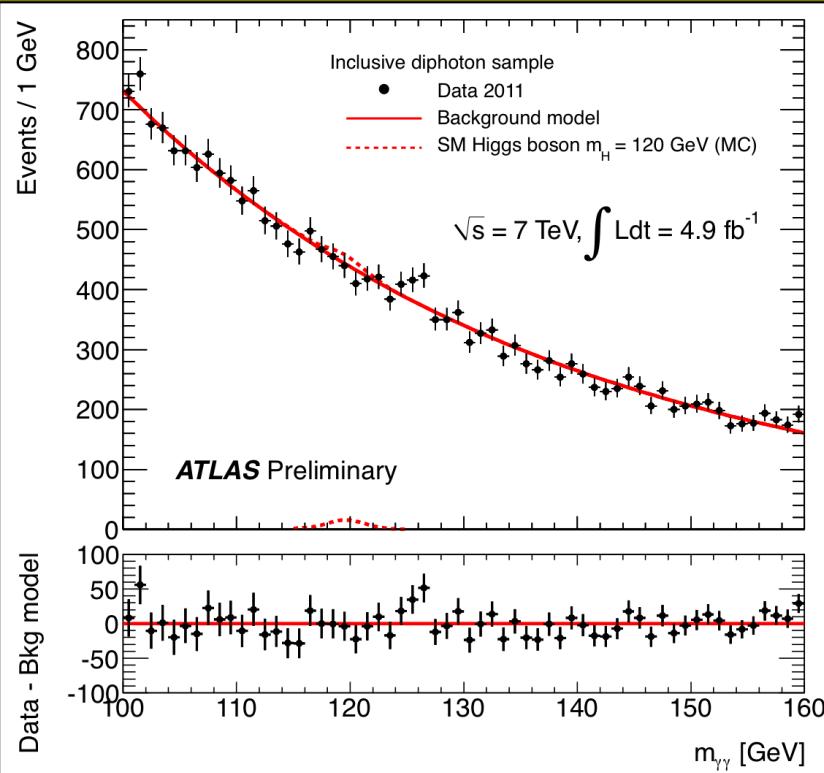

Photon isolation requirement:  $E_T < 5$  GeV inside a cone  $\Delta R < 0.4$  around  $\gamma$  direction.  
Underlying event and pile-up contribution subtracted using an "ambient energy density" determined event-by-event.

If the subtraction is not perfect, a residual dependence of the corrected isolation energy on the bunch position in the train is observed, due to the impact of pile-up from neighbouring bunches convolved with the LAr calorimeter pulse shape.

## After all selections: kinematic cuts, $\gamma$ identification and isolation

- 22489 events with  $100 < m_{\gamma\gamma} < 160$  GeV observed in the data
- expected signal efficiency:  $\sim 35\%$  for  $m_H=125$  GeV

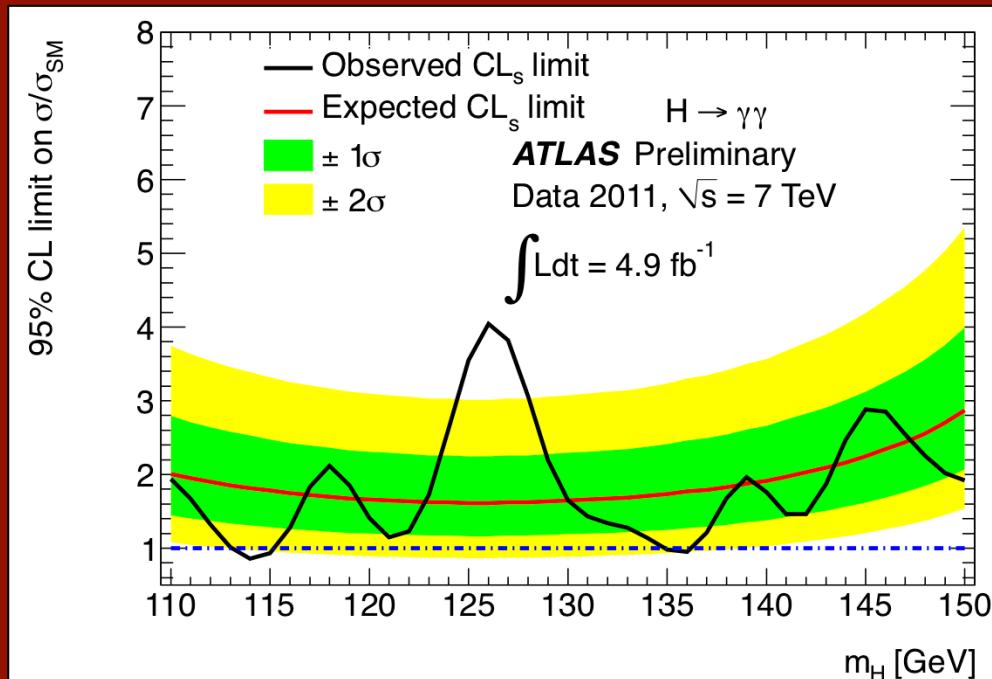

$m_{\gamma\gamma}$  spectrum fit with exponential function for background plus Crystal Ball + Gaussian for signal  
 $\rightarrow$  background determined directly from data

### Main systematic uncertainties

- Expected signal yield :  $\sim 20\%$
- $H \rightarrow \gamma\gamma$  mass resolution :  $\sim 14\%$
- $H \rightarrow \gamma\gamma p_T$  modeling :  $\sim 8\%$
- Background modeling :  $\pm 0.1\text{--}5.6$  events

### Systematic uncertainties on signal expectation

Event yield	
Photon reconstruction and identification	$\pm 11\%$
Effect of pileup on photon identification	$\pm 4\%$
Isolation cut efficiency	$\pm 5\%$
Trigger efficiency	$\pm 1\%$
Higgs boson cross section	$+15\% / -11\%$
Higgs boson $p_T$ modeling	$\pm 1\%$
Luminosity	$\pm 3.9\%$
Mass resolution	
Calorimeter energy resolution	$\pm 12\%$
Photon energy calibration	$\pm 6\%$
Effect of pileup on energy resolution	$\pm 3\%$
Photon angular resolution	$\pm 1\%$
Migration	
Higgs boson $p_T$ modeling	$\pm 8\%$
Conversion reconstruction	$\pm 4.5\%$

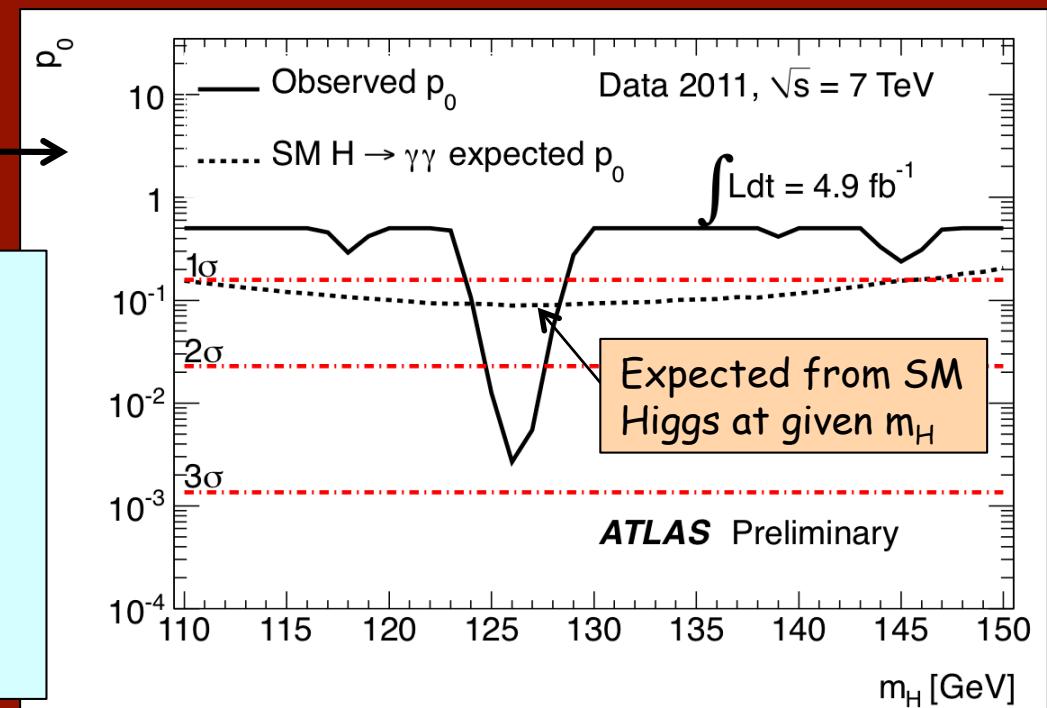

Excluded (95% CL):  
 $114 \leq m_H \leq 115 \text{ GeV}, 135 \leq m_H \leq 136 \text{ GeV}$

Consistency of the data with the background-only expectation

Maximum deviation from background-only expectation observed for  $m_H \sim 126$  GeV:

- local  $p_0$ -value: 0.27% or  $2.8\sigma$
- expected from SM Higgs:  $\sim 1.4\sigma$  local
- global  $p_0$ -value: includes probability for such an excess to appear anywhere in the investigated mass range (110-150 GeV) ("Look-Elsewhere-Effect"):  $\sim 7\%$  ( $1.5\sigma$ )

$H \rightarrow ZZ^{(*)} \rightarrow 4l$  ( $4e, 4\mu, 2e2\mu$ )

$110 < m_H < 600$  GeV

- $\sigma \sim 2-5$  fb
- However:
  - mass can be fully reconstructed  $\rightarrow$  events would cluster in a (narrow) peak
  - pure:  $S/B \sim 1$
- 4 leptons:  $p_T^{1,2,3,4} > 20, 20, 7, 7$  GeV;  $m_{12} = m_Z \pm 15$  GeV;  $m_{34} > 15-60$  GeV (depending on  $m_H$ )
- Main backgrounds:
  - $ZZ^{(*)}$  (irreducible)
  - $m_H < 2m_Z$ : Zbb, Z+jets, tt with two leptons from b/q-jets  $\rightarrow l$
- Suppressed with isolation and impact parameter cuts on two softest leptons
- Signal acceptance  $\times$  efficiency:  $\sim 15\%$  for  $m_H \sim 125$  GeV

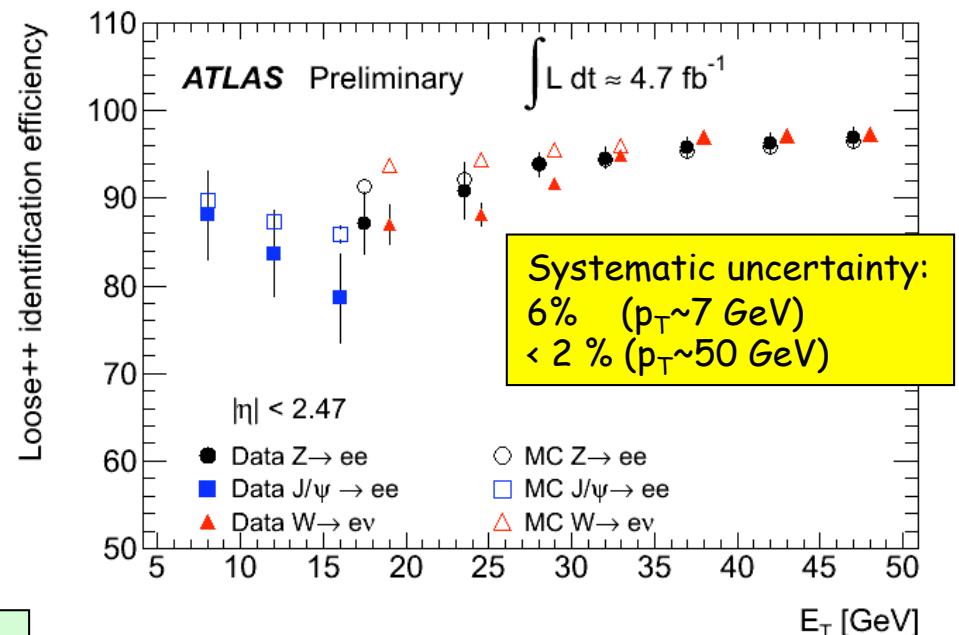

Crucial experimental aspects:

- High lepton reconstruction and identification efficiency down to lowest  $p_T$
- Good lepton energy/momentum resolution
- Good control of reducible backgrounds (Zbb, Z+jets, tt) in low-mass region:
  - $\rightarrow$  cannot rely on MC alone (theoretical uncertainties, b/q-jet  $\rightarrow l$  modeling, ..)
  - $\rightarrow$  need to compare MC to data in background-enriched control regions (but: low statistics ..)
- Conservative/stringent  $p_T$  and  $m(l)$  cuts used at this stage

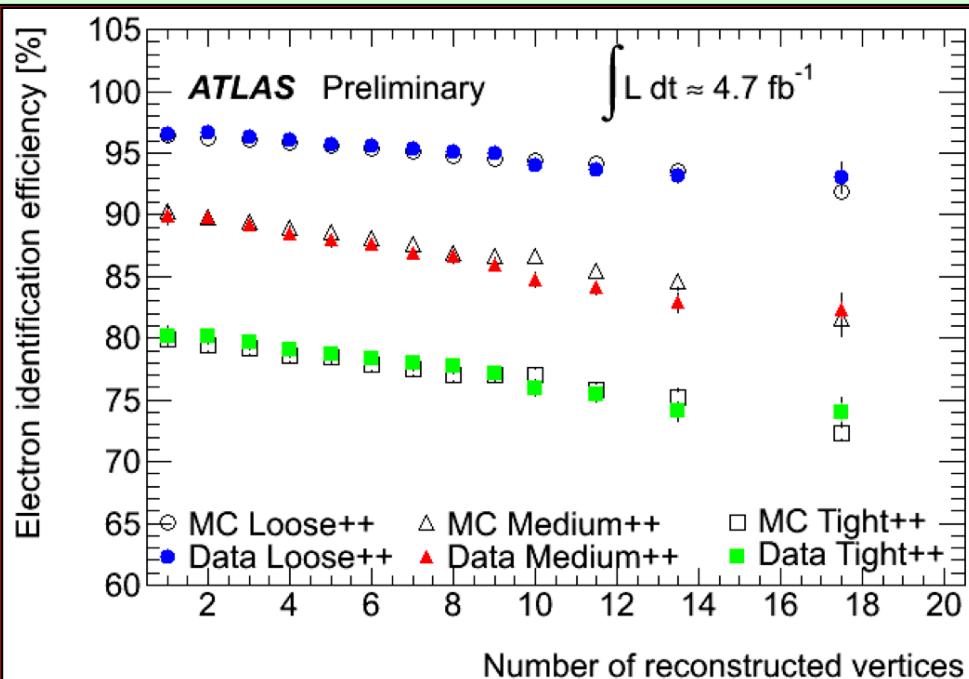

Identification efficiency from  
 $J/\psi \rightarrow ee$ ,  $W \rightarrow ev$ ,  $Z \rightarrow ee$  data samples

Crucial to understand low- $p_T$  electrons  
(affected by material) with data

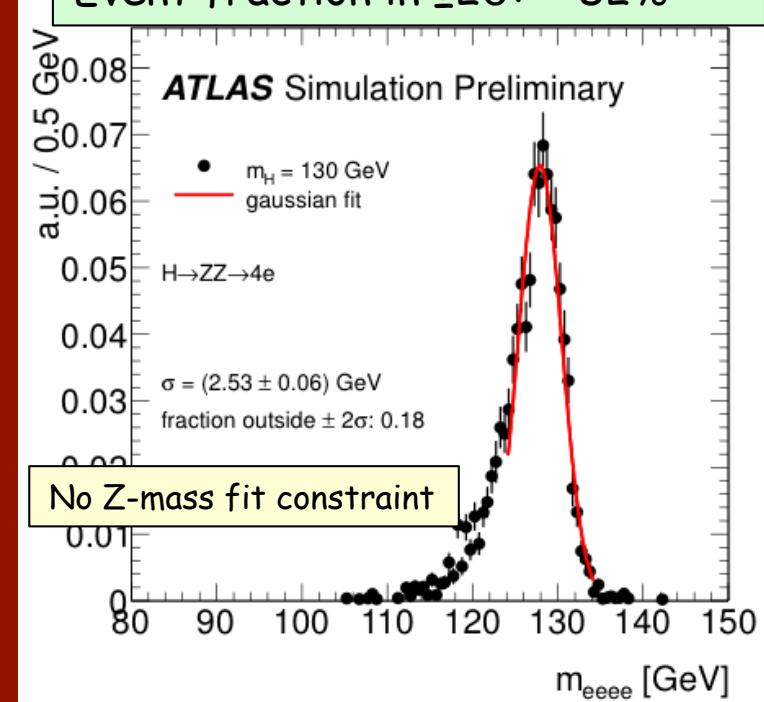

### Electron performance

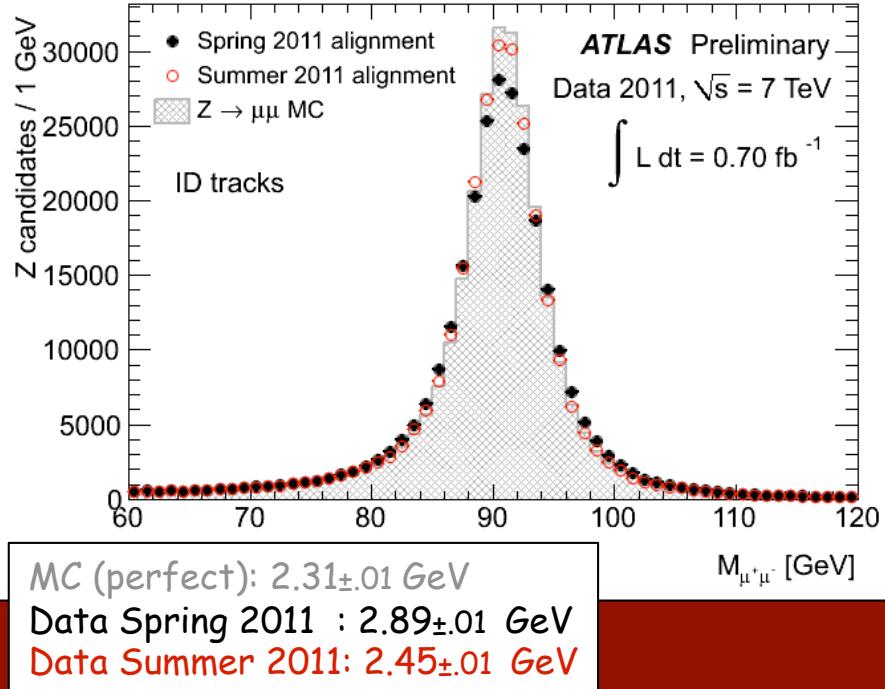

Variation of electron efficiency with  
pile-up (cuts not re-tuned yet) well modeled by  
simulation: from  $Z \rightarrow ee$  data and MC samples

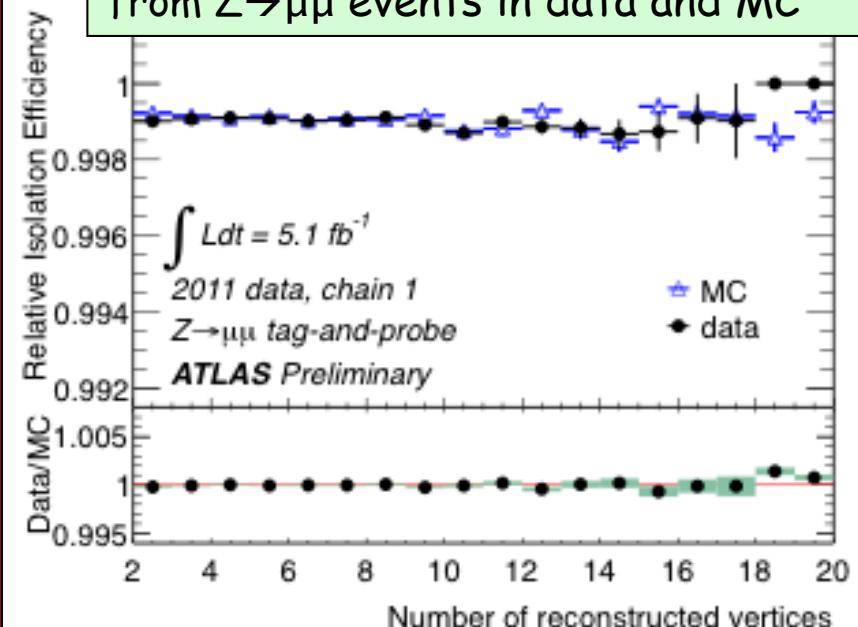

$H \rightarrow 4e$  mass resolution: 2.5 GeV  
Event fraction in  $\pm 2\sigma$ : ~ 82%

## Improving $Z \rightarrow \mu\mu$ mass resolution

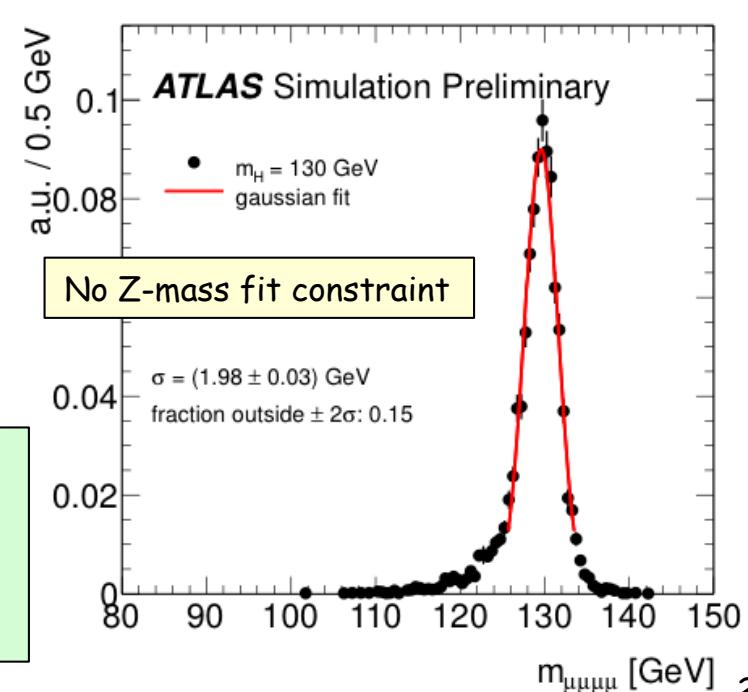

## Muon (calorimetric) isolation efficiency from $Z \rightarrow \mu\mu$ events in data and MC

## Muon performance

Muon reconstruction efficiency > 95% over  $4 < p < 100$  GeV

$H \rightarrow 4\mu$  mass resolution:  $\sim 2$  GeV  
Event fraction in  $\pm 2\sigma$ :  $\sim 85\%$

## After all selections: kinematic cuts, isolation, impact parameter

Full mass range

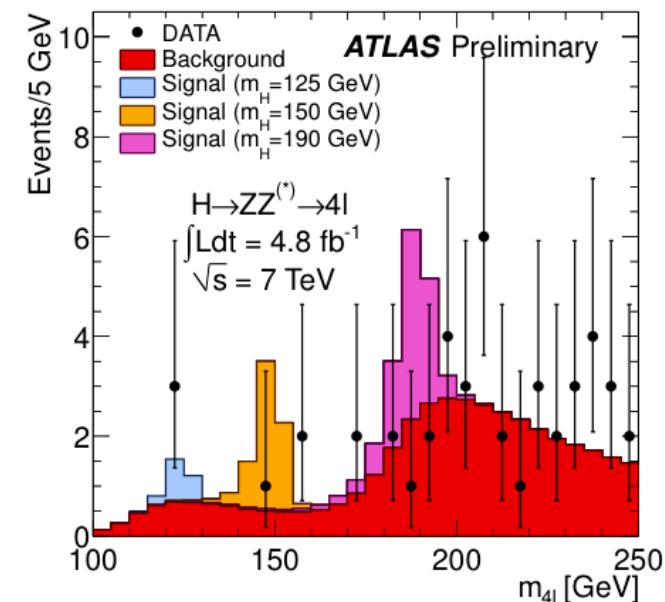

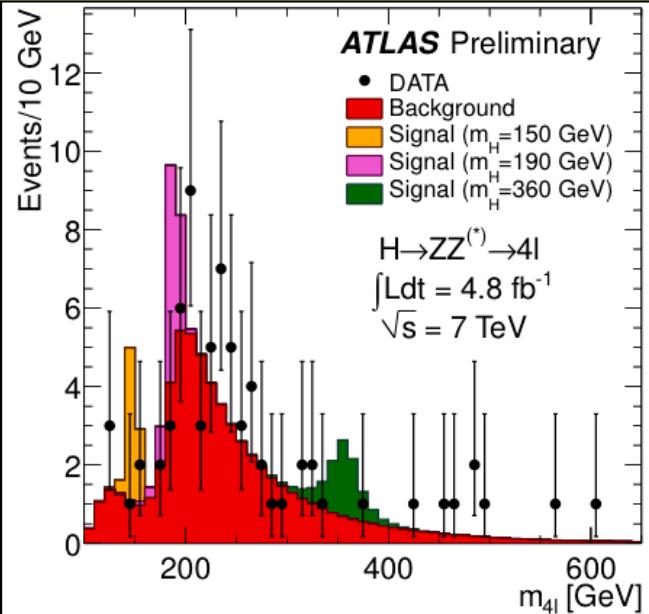

Observed: 71 events: 24 4 $\mu$  + 30 2e2 $\mu$  + 17 4e

Expected from background:  $62 \pm 9$

$m(4l) < 180$  GeV

Observed: 8 events: 3 4 $\mu$  + 3 2e2 $\mu$  + 2 4e

Expected from background:  $9.3 \pm 1.5$

In the region  $m_H < 141$  GeV (not already excluded at 95% C.L.) 3 events are observed:  
two 2e2 $\mu$  events ( $m=123.6$  GeV,  $m=124.3$  GeV) and one 4 $\mu$  event ( $m=124.6$  GeV)

In the region  $117 < m_{4l} < 128$  GeV

(containing ~90% of a  $m_H=125$  GeV signal):

- similar contributions expected from signal and background: ~ 1.5 events each
- S/B ~ 2 (4 $\mu$ ), ~ 1 (2e2 $\mu$ ), ~ 0.3 (4e)
- Background dominated by ZZ\* (4 $\mu$  and 2e2 $\mu$ ), ZZ\* and Z+jets (4e)

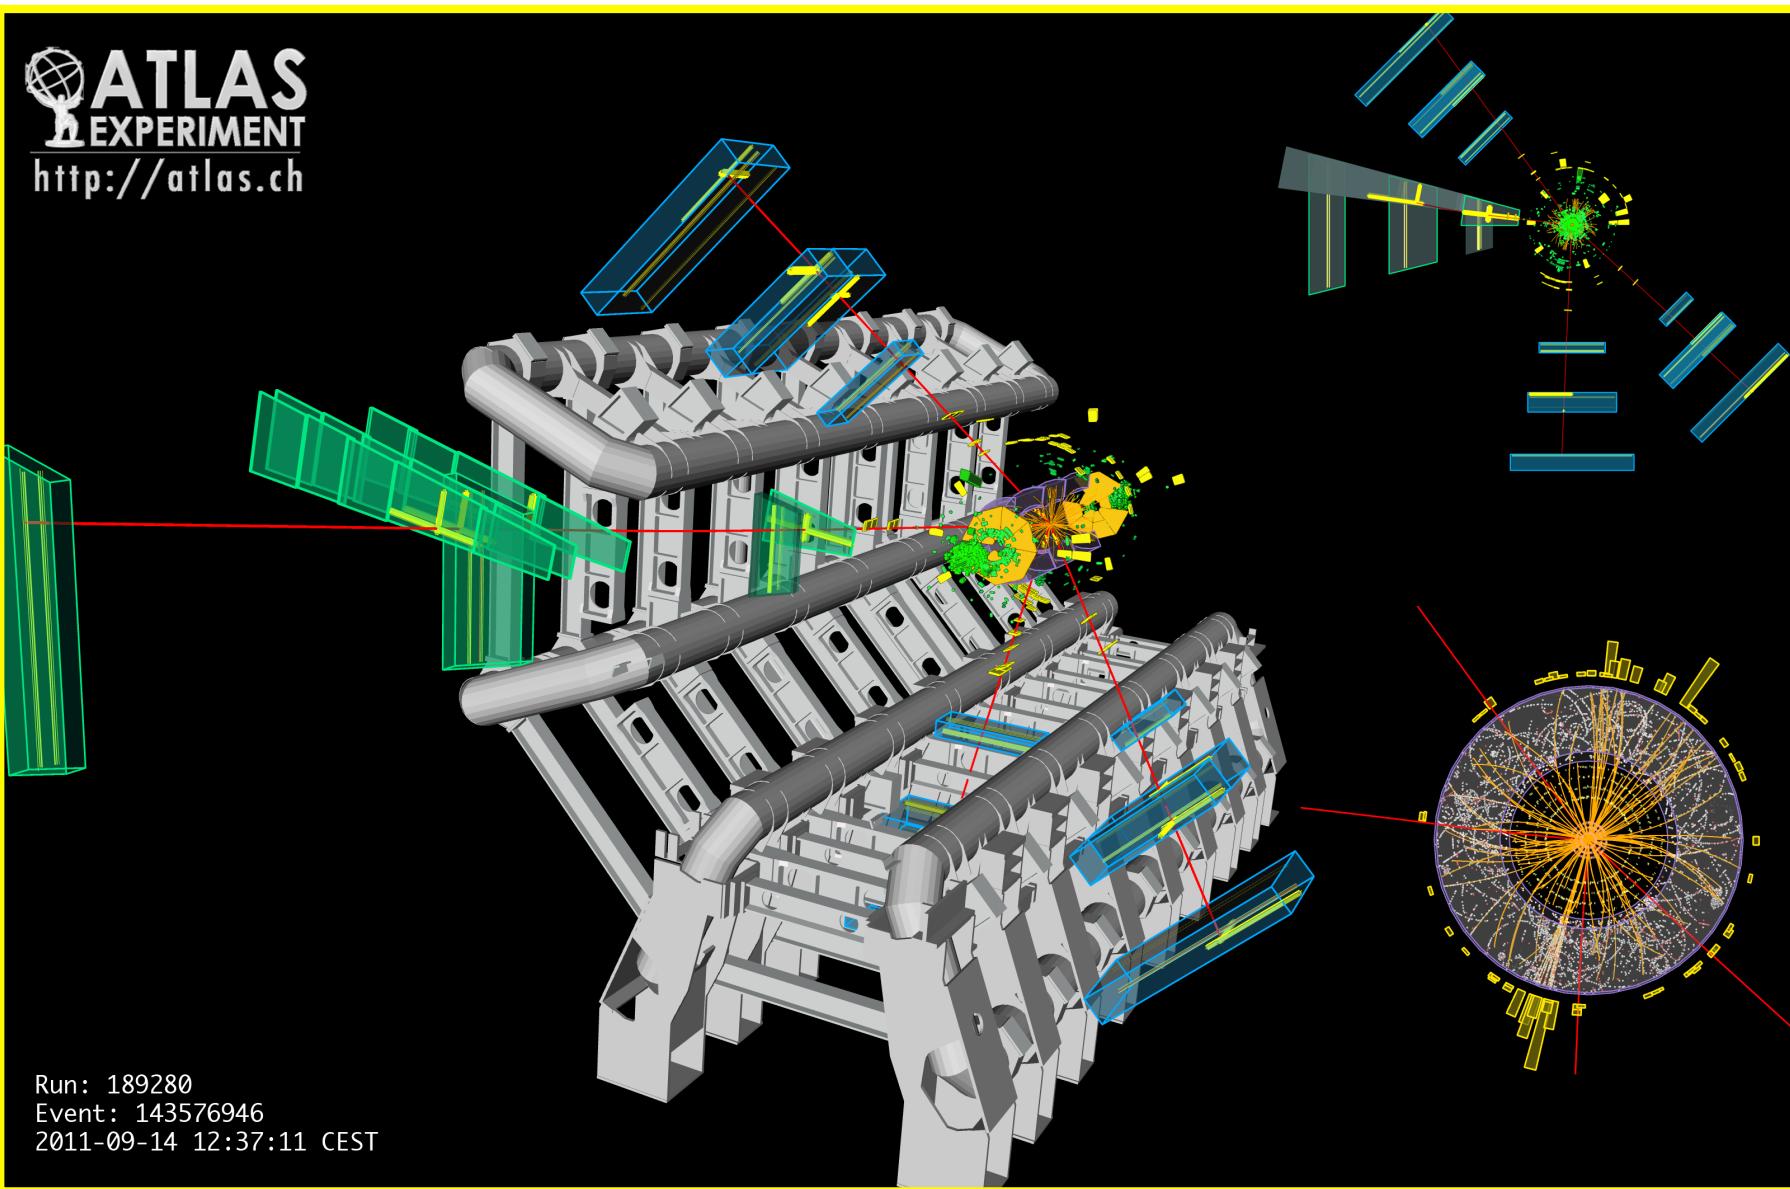

Main systematic uncertainties

Higgs cross-section	: ~ 15%
Electron efficiency	: ~ 2-8%
ZZ* background	: ~ 15%
Zbb, +jets backgrounds	: ~ 40%

4 $\mu$  candidate with  $m_{4\mu} = 124.6$  GeV

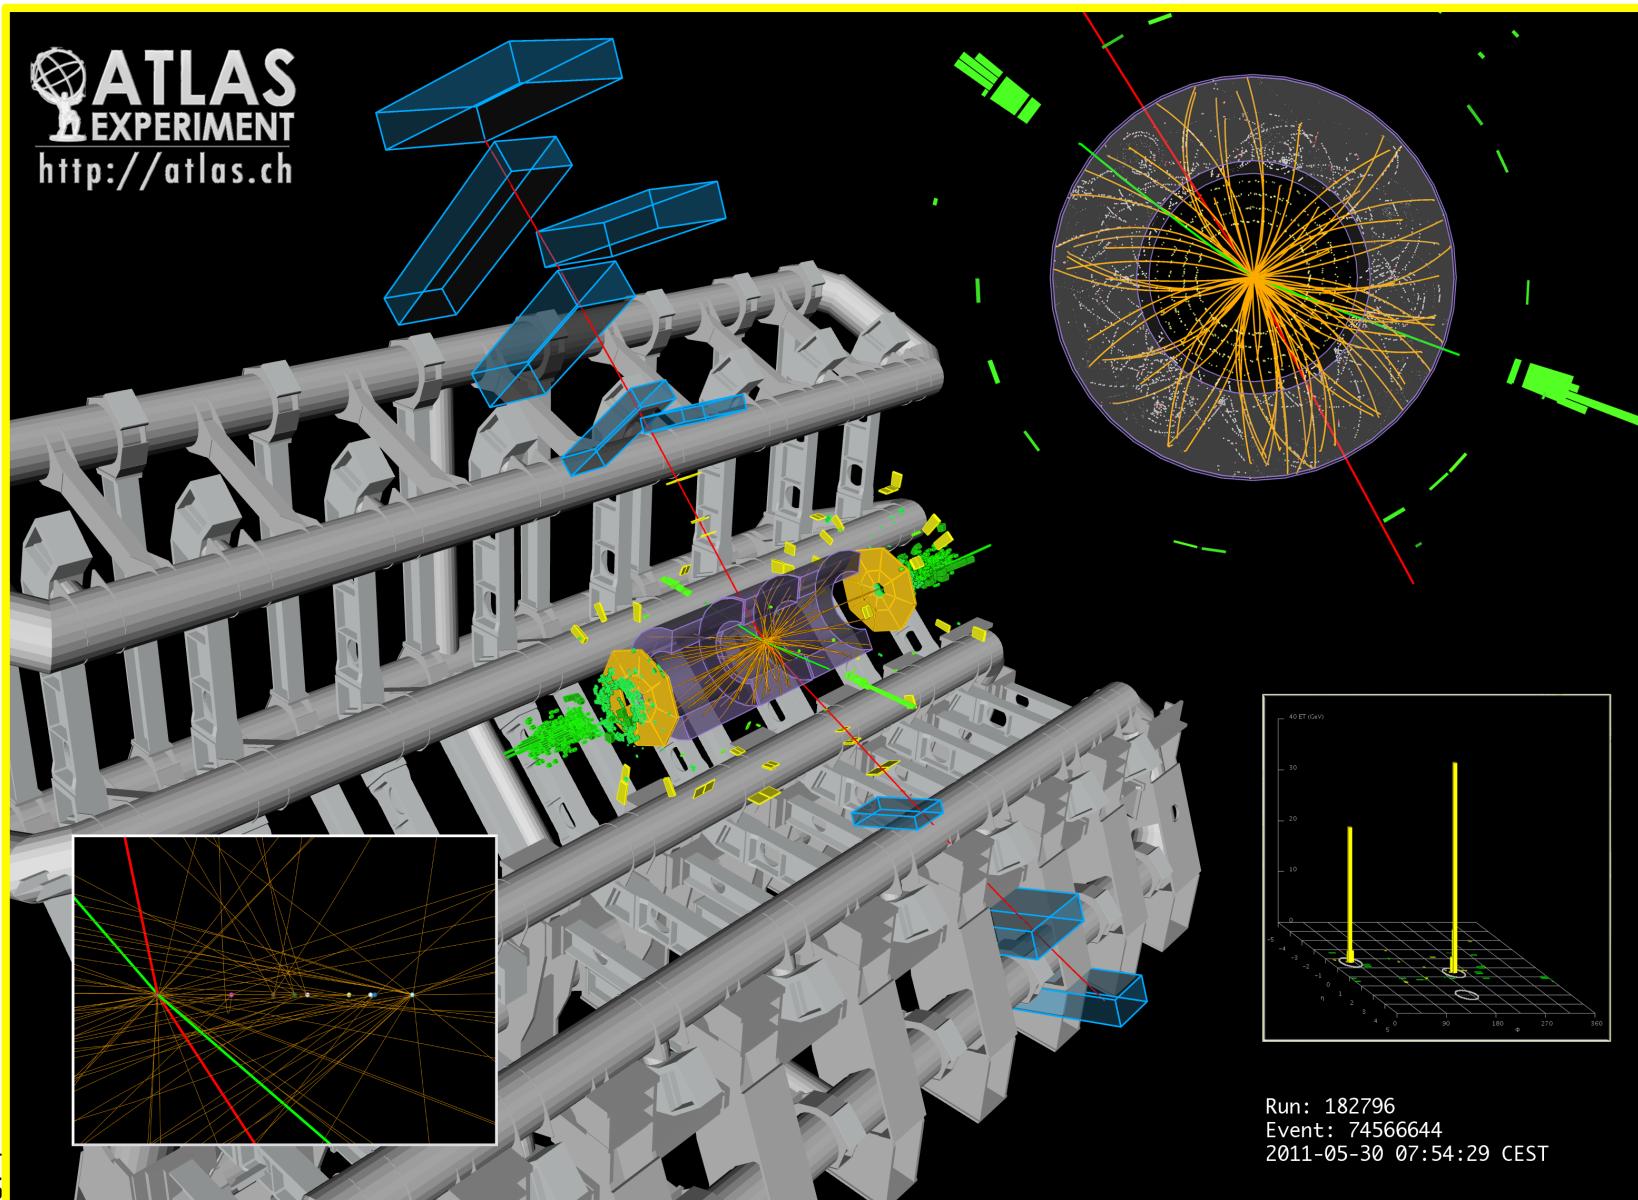

$p_T(\mu^-, \mu^+, \mu^+, \mu^-) = 61.2, 33.1, 17.8, 11.6$  GeV

$m_{12} = 89.7$  GeV,  $m_{34} = 24.6$  GeV

## 2e2 $\mu$ candidate with $m_{2e2\mu} = 124.3$ GeV

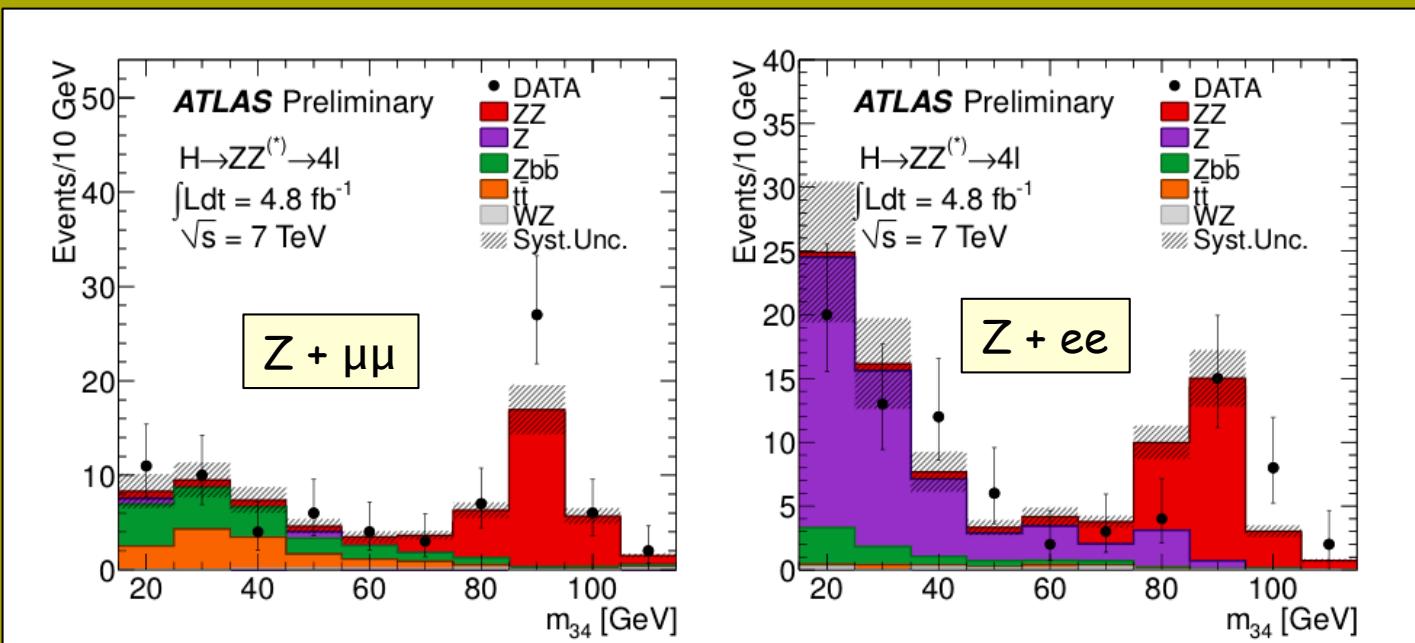

$p_T(e^+, e^-, \mu^-, \mu^+) = 41.5, 26.5, 24.7, 18.3$  GeV  
 $m(e^+e^-) = 76.8$  GeV,  $m(\mu^+\mu^-) = 45.7$  GeV

Reducible backgrounds from  $Zbb$ ,  $Z+jets$ ,  $t\bar{t}$  giving 2 genuine + 2 fake leptons measured using background-enriched-signal-depleted control regions in data mimicking as much as possible the kinematics of the signal region → compromise between statistics and "purity"

$Zbb+Z+jets$  control regions: events with:

- 2 opposite-sign same-flavour leptons,  $m_{ll} = m_Z \pm 15$  GeV
- 2 additional same-flavour leptons passing all cuts but isolation and impact parameter  
→ below plots of their invariant mass ( $m_{34}$ )

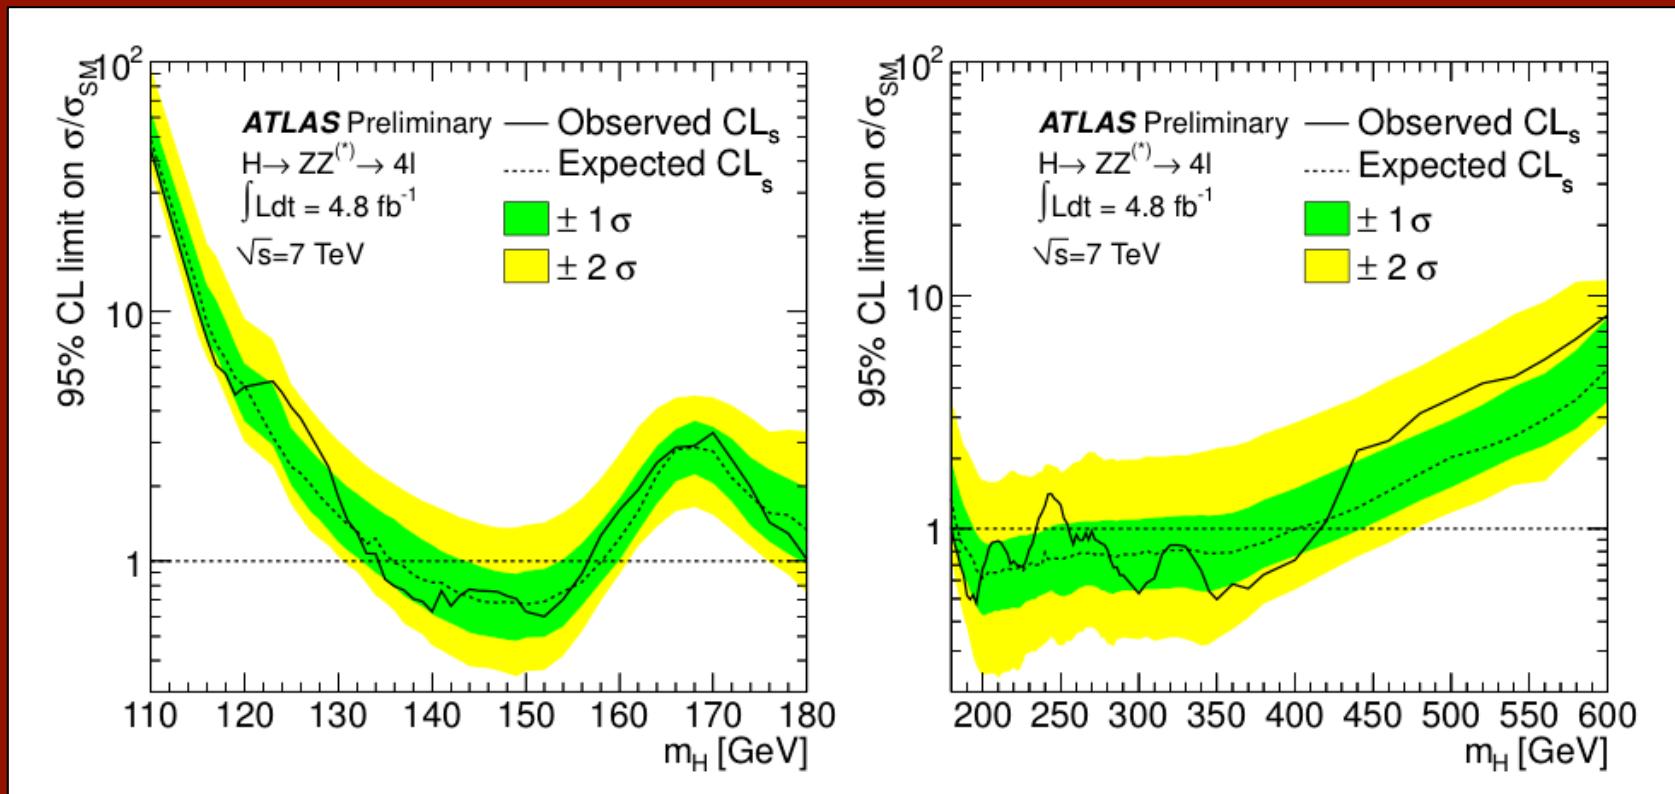

- Low-mass regions dominated by  $Zbb$  ( $Z+\mu^+\mu^-$  sample) and  $Z+jet$  ( $Z+e^+e^-$  sample)
- Data well reproduced by MC (within uncertainties)
- Samples of  $Z+\mu$  and  $Z+e$  then used to compare efficiencies of isolation and impact parameter cuts between data and MC → Good agreement  
→ MC used to estimate background contamination in signal region

→

	Data	MC
$Z+\mu$	$20 \pm 1\%$	$20.3 \pm 0.4\%$
$Z+e$	$29.9 \pm 0.6\%$	$30.4 \pm 0.4\%$

## From fit of signal and background expectations to 4l mass spectrum

Excluded (95% CL):  $135 < m_H < 156 \text{ GeV}$  and  $181 < m_H < 415 \text{ GeV}$  (except 234-255 GeV)  
 Expected (95% CL):  $137 < m_H < 158 \text{ GeV}$  and  $185 < m_H < 400 \text{ GeV}$

## Consistency of the data with the background-only expectation

### Maximum deviations from background-only expectations

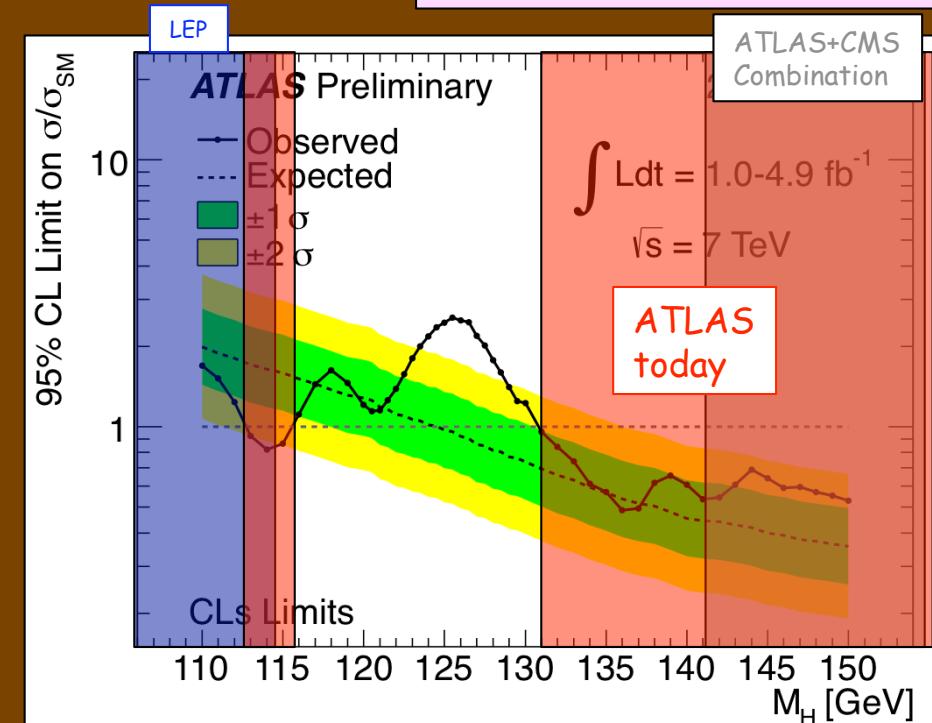

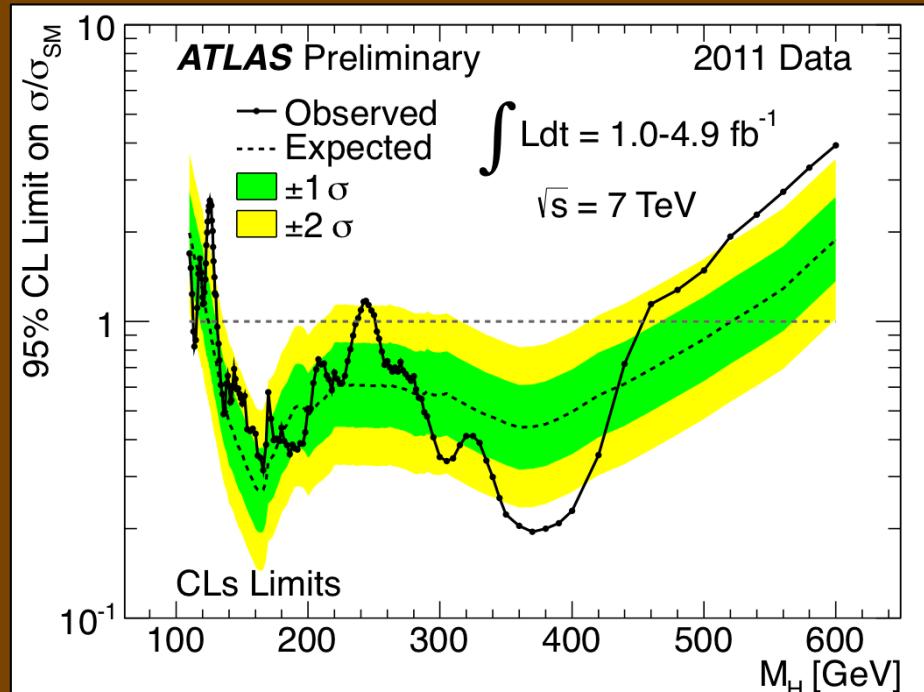

Excluded at  
95% C.L. by  
ATLAS+CMS  
combination

$m_H$ (GeV)	Local (global) $p_0$	Local significance	Expected from SM Higgs
125	1.8% (~50%)	2.1 $\sigma$	1.4 $\sigma$
244	1.1% (~50%)	2.3 $\sigma$	3.2 $\sigma$
500	1.4% (~50%)	2.2 $\sigma$	1.5 $\sigma$

LEE estimated over  
mass range: 110-600 GeV

Putting all channels together → combined constraints

$H \rightarrow \gamma\gamma, H \rightarrow \tau\tau$   
 $H \rightarrow WW^{(*)} \rightarrow llvv$   
 $H \rightarrow ZZ^{(*)} \rightarrow 4l, H \rightarrow ZZ \rightarrow llvv$   
 $H \rightarrow ZZ \rightarrow llqq, H \rightarrow WW \rightarrow lvqq$   
 W/ZH → lbb+X not included

Excluded at 95% CL

$112.7 < m_H < 115.5 \text{ GeV}$   
 $131 < m_H < 453 \text{ GeV, except } 237-251 \text{ GeV}$

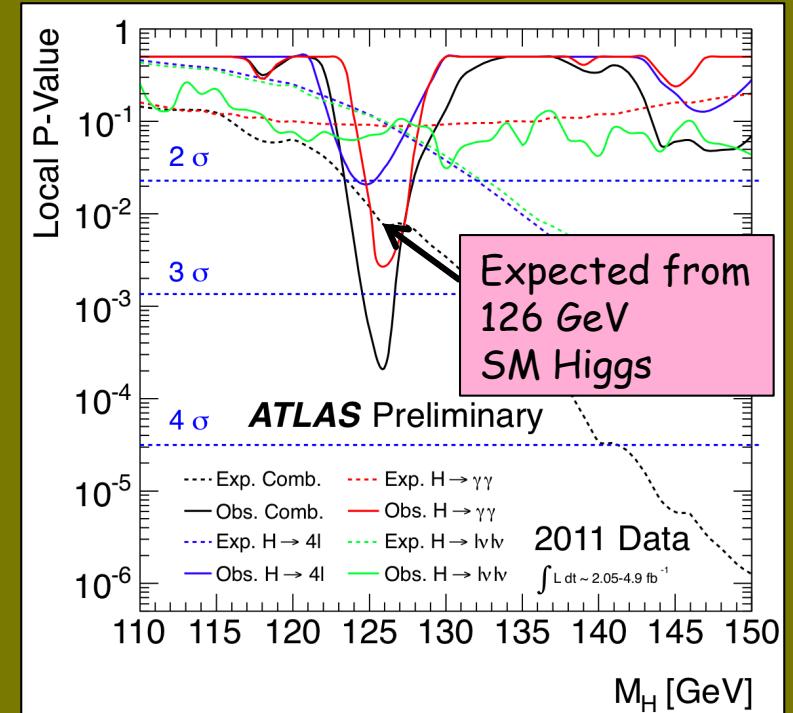

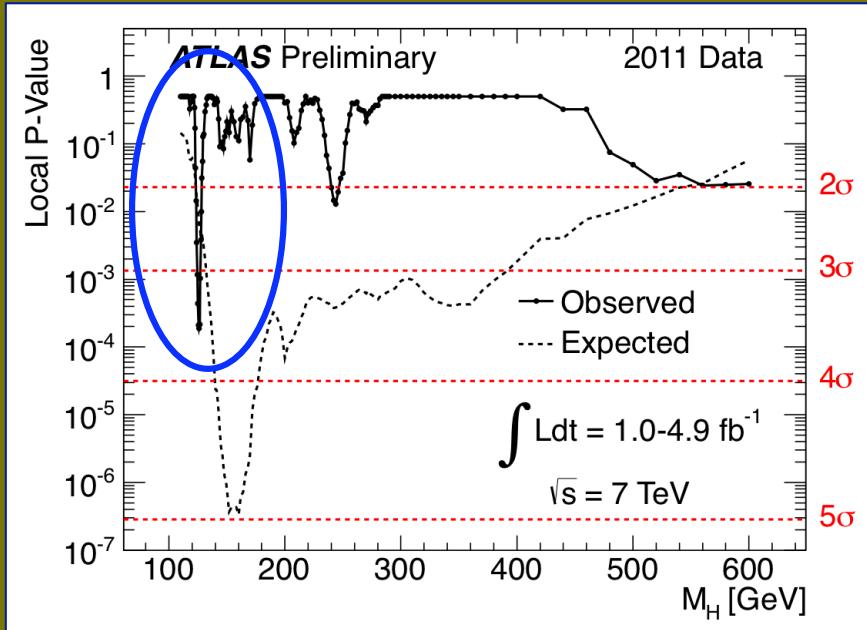

Expected if no signal

124.6-520 GeV

Excluded at 99% CL

$133 < m_H < 230 \text{ GeV}, 260 < m_H < 437 \text{ GeV}$

# Consistency of the data with the background-only expectation

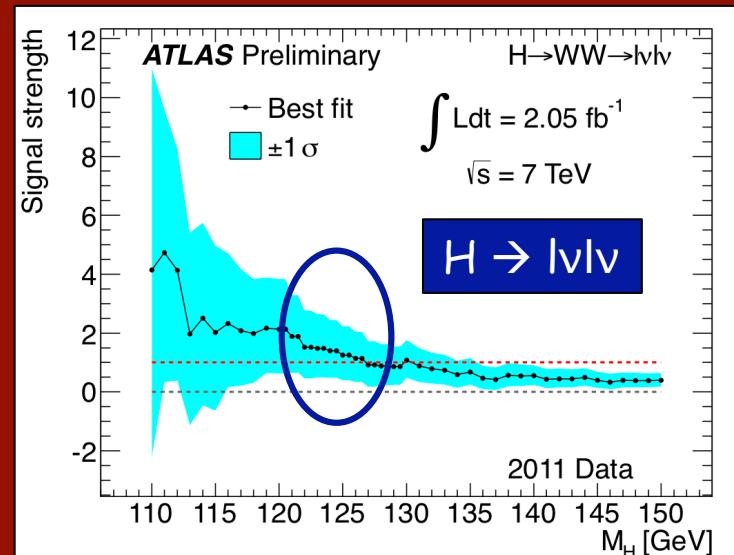

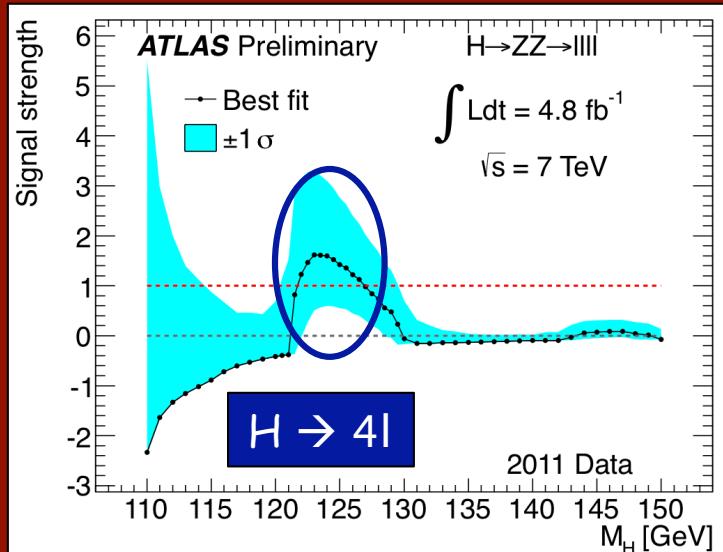

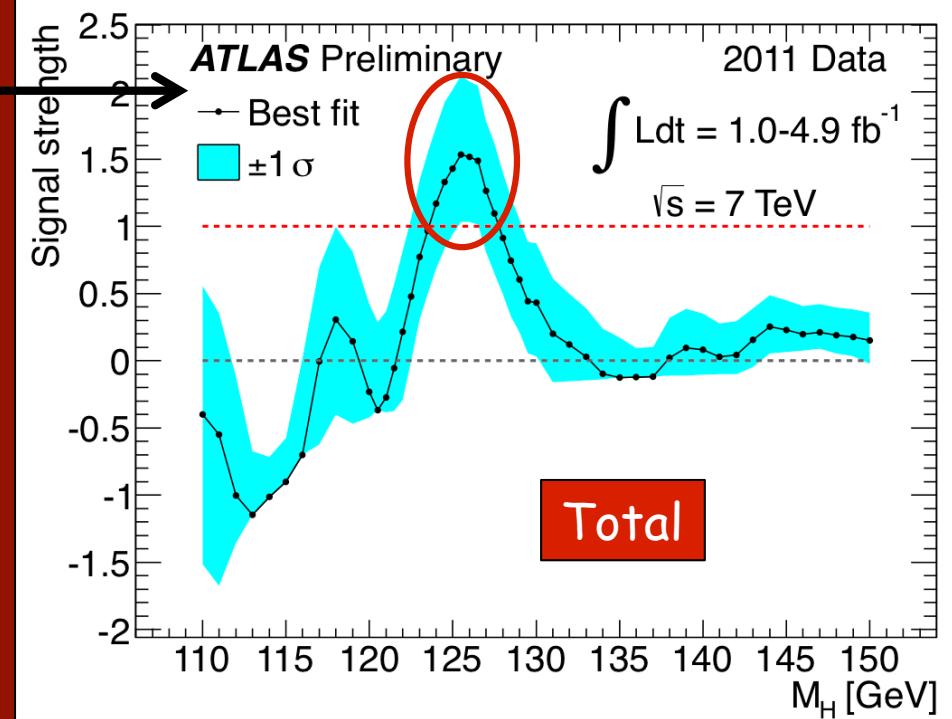

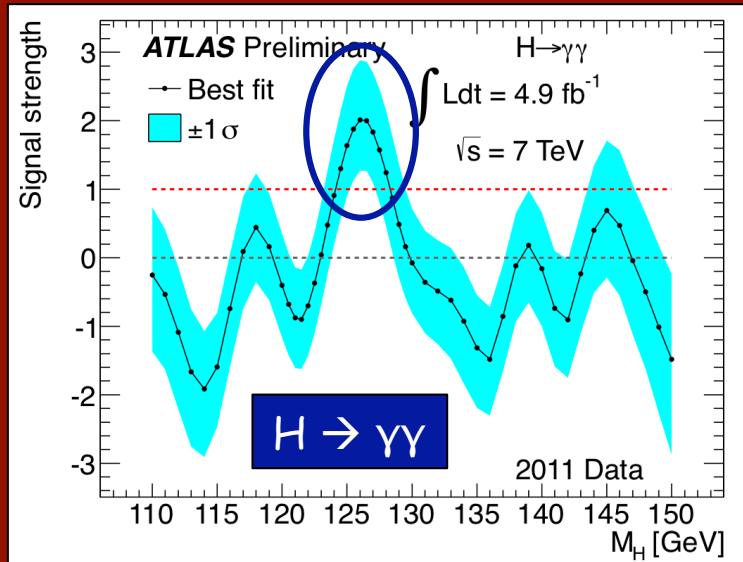

Maximum deviation from background-only expectation observed for  $m_H \sim 126 \text{ GeV}$

Local  $p_0$ -value:  $1.9 \cdot 10^{-4}$   
 → local significance of the excess:  $3.6\sigma$   
 $\sim 2.8\sigma H \rightarrow \gamma\gamma$ ,  $2.1\sigma H \rightarrow 4l$ ,  $1.4\sigma H \rightarrow l\nu l\nu$

Expected from SM Higgs:  $\sim 2.4\sigma$  local ( $\sim 1.4\sigma$  per channel)

Global  $p_0$ -value :  $0.6\% \rightarrow 2.5\sigma$  LEE over  $110-146 \text{ GeV}$   
 Global  $p_0$ -value :  $1.4\% \rightarrow 2.2\sigma$  LEE over  $110-600 \text{ GeV}$

## Compatibility of the observation with the expected strength of a SM Higgs signal

The observed excess is slightly larger ( $2 \pm 0.8$ ) than expected in the  $H \rightarrow \gamma\gamma$  channel and compatible within  $1\sigma$  for the other channels and the combined result

### Improve analysis sensitivities:

- update  $H \rightarrow WW^{(*)} \rightarrow l l l l$ ,  $W/ZH \rightarrow bb$  and  $H \rightarrow \tau\tau$  to  $\sim 5 \text{ fb}^{-1}$
- relax kinematic cuts (e.g. lepton  $p_T$ ) to increase acceptance at low masses
- multivariate techniques, exclusive channels (e.g  $H \rightarrow \gamma\gamma + 0/1/2$  jets), additional discriminating variables beyond mass spectra ( $p_T$ , angular distributions, etc.)

In parallel: improvements of the detector performance and modeling (a never-ending feat ...)

One of the numerous lessons and outstanding achievements of the Tevatron:  
how much better than expectation experiments can do with data and ingenuity !

Combine with CMS: being discussed ...

Not before results from individual experiments are published

### MORE DATA $\rightarrow$ 2012 run:

- $\sim 20 \text{ fb}^{-1}$  more per experiment of delivered luminosity needed for:
- $5\sigma$  discovery at  $m_H \sim 125 \text{ GeV}$  with  $\sim 3\sigma$  per channel (ATLAS alone)
  - $5\sigma$  discovery down to  $\sim 116 \text{ GeV}$  (ATLAS+CMS combined)
- "Contingency": analysis improvements;  $\sqrt{s}=8 \text{ TeV}$  (brings  $\sim 10\%$  sensitivity gain)

## Conclusions

It has been a wonderful year for the LHC and ATLAS → THANKS LHC TEAM !

We have looked for a SM Higgs boson

- over the mass region 110-600 GeV
- in 11 distinct channels
- using up to  $4.9 \text{ fb}^{-1}$  of integrated luminosity

We have restricted the most likely mass region (95% CL) to

**115.5-131 GeV**

We observe an excess of events around  $m_H \sim 126 \text{ GeV}$ :

- local significance  $3.6\sigma$ , with contributions from the  $H \rightarrow \gamma\gamma$  ( $2.8\sigma$ ),  $H \rightarrow ZZ^* \rightarrow 4l$  ( $2.1\sigma$ ),  $H \rightarrow WW^{(*)} \rightarrow llvv$  ( $1.4\sigma$ ) analyses
- SM Higgs expectation:  $2.4\sigma$  local → observed excess compatible with signal strength within  $+1\sigma$
- the global significance (taking into account Look-Elsewhere-Effect) is  **$\sim 2.3\sigma$**

It would be a very nice region for the Higgs to be → accessible at LHC in  $\gamma\gamma$ ,  $4l$ ,  $llvv$ ,  $bb$ ,  $\tau\tau$

It's too early to draw definite conclusions

More studies and more data are needed

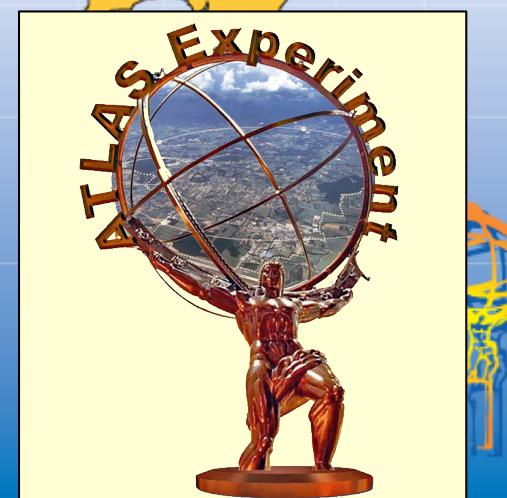

We have built solid foundations for the (exciting !) months to come

What an extraordinary time !

## ATLAS Collaboration

# SPARES

ATLAS-CONF-2011-161 (13 December 2011)

Search for the Standard Model Higgs boson in the diphoton decay channel  
with  $4.9 \text{ fb}^{-1}$  of ATLAS data at  $\sqrt{s}=7 \text{ TeV}$

ATLAS-CONF-2011-162 (13 December 2011)

Search for the Standard Model Higgs boson in the decay channel  $H \rightarrow ZZ^{(*)} \rightarrow 4l$   
with  $4.8 \text{ fb}^{-1}$  of pp collisions at  $\sqrt{s}=7 \text{ TeV}$

ATLAS-CONF-2011-163 (13 December 2011)

Combination of Higgs Boson searches with up to  $4.9 \text{ fb}^{-1}$  of pp collisions data  
taken at a center-of-mass energy of  $7 \text{ TeV}$  with the ATLAS experiment at the LHC

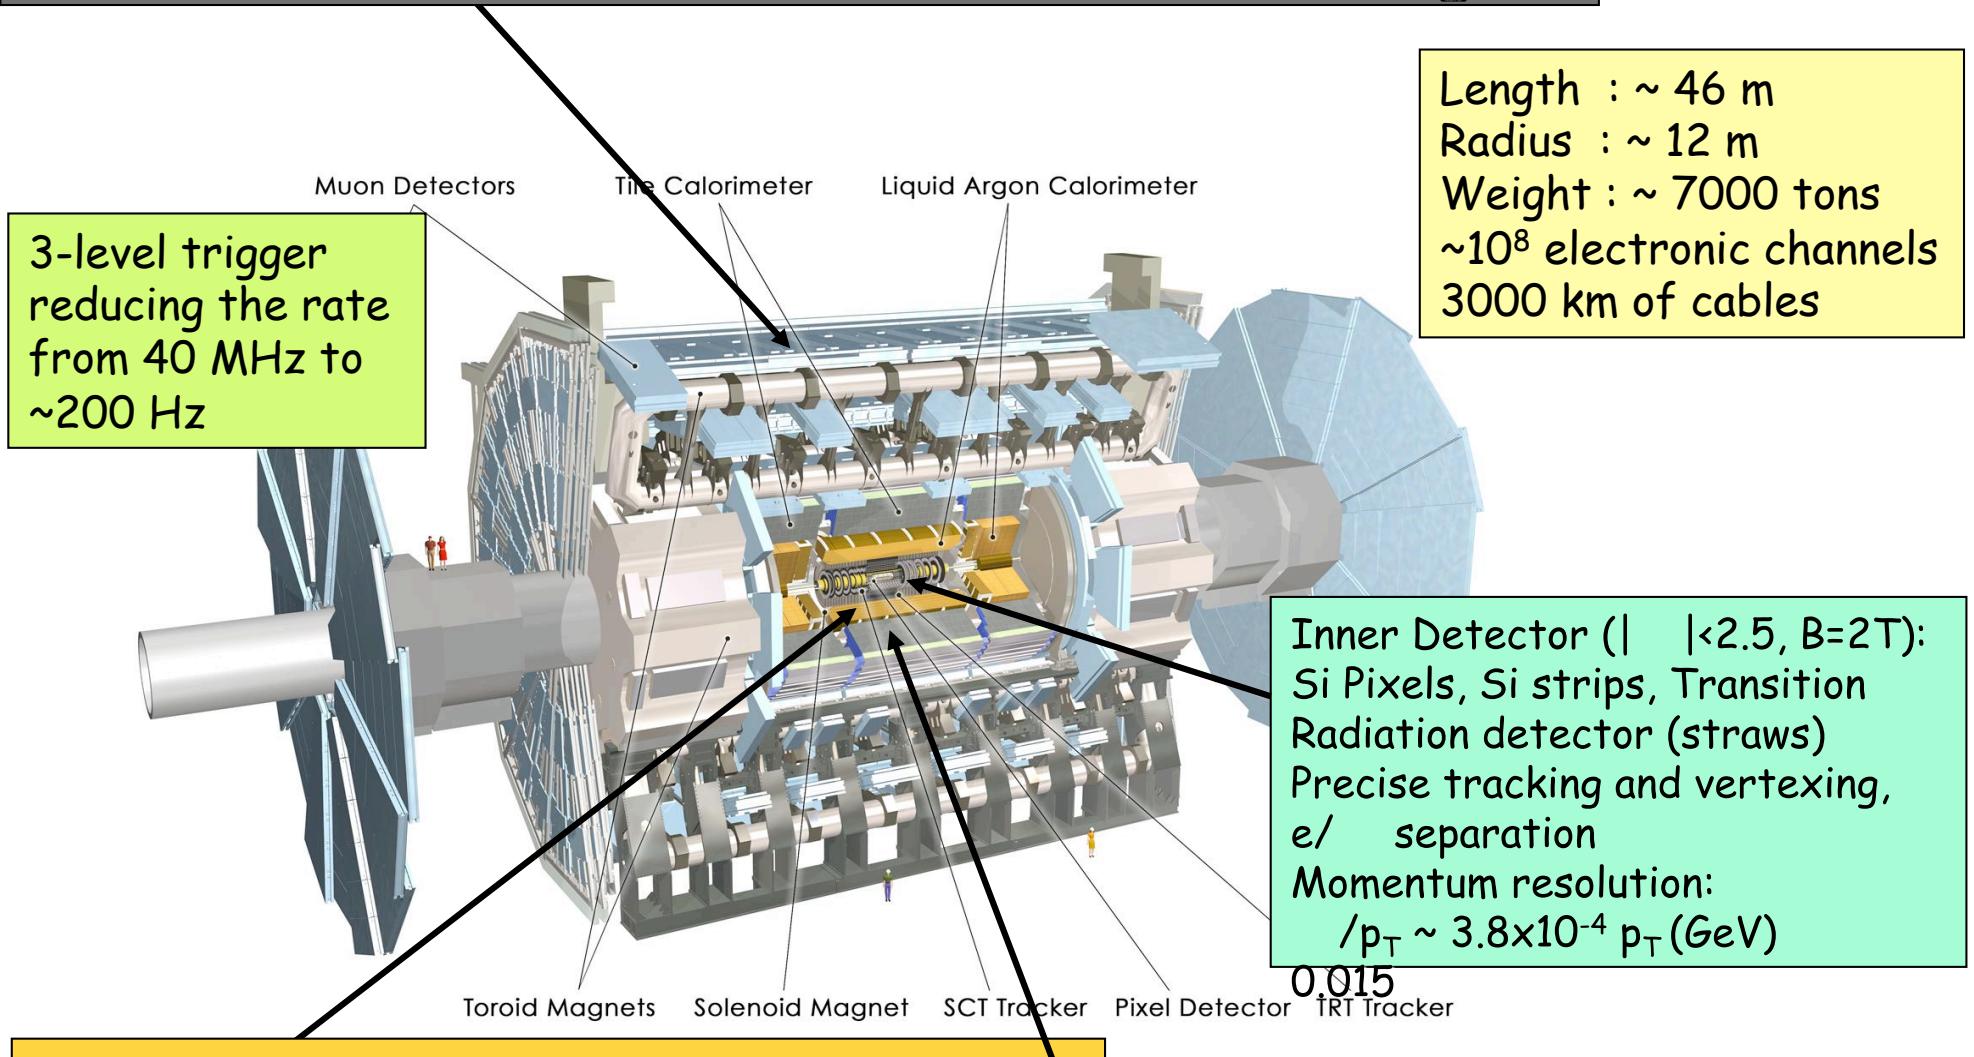

Submitted to PRL (12 December 2011)

Search for the Higgs boson in the  $H \rightarrow WW^{(*)} \rightarrow llvv$  decay channel in  
pp collisions at  $\sqrt{s}=7 \text{ TeV}$  with the ATLAS detector

CONF notes available after the seminar at:

<https://atlas.web.cern.ch/Atlas/GROUPS/PHYSICS/CONFNOTES/>

Muon Spectrometer ( $|y| < 2.7$ ) : air-core toroids with gas-based muon chambers  
 Muon trigger and measurement with momentum resolution  $< 10\%$  up to  $\sqrt{E_T} \sim 1 \text{ TeV}$

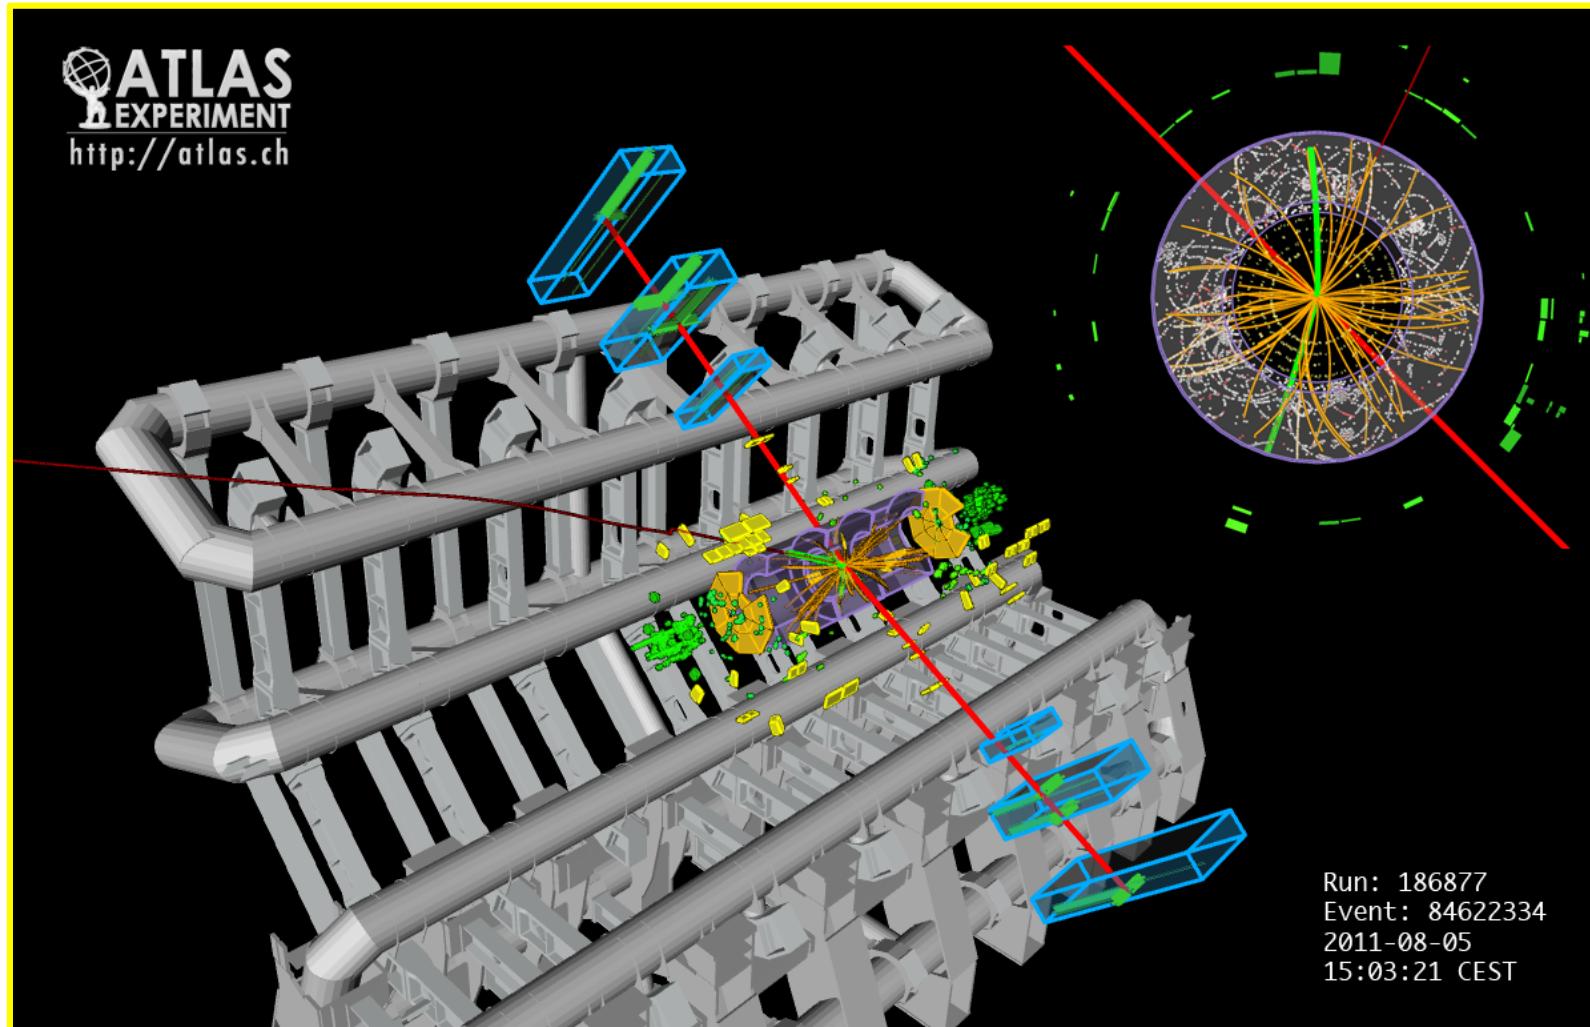

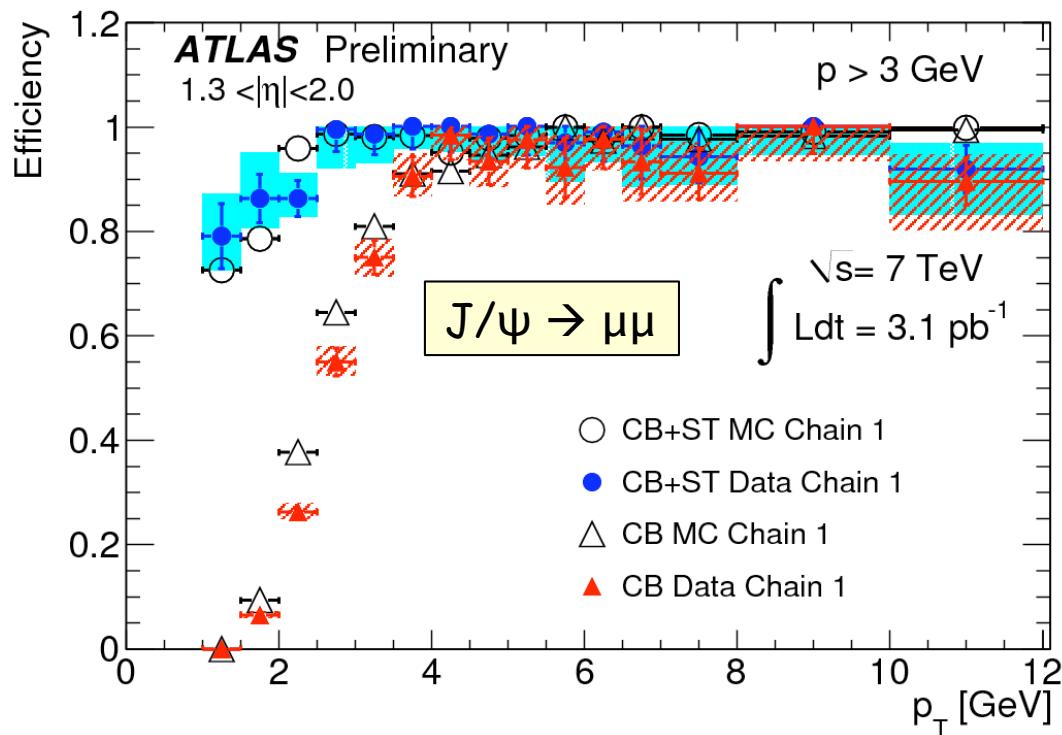

## 2011 Physics Proton Trigger Menu (end of run L = $3.3 \cdot 10^{33} \text{ cm}^{-2}\text{s}^{-1}$ )

	Offline Selection	Trigger Selection		L1 Rate (kHz) at 3e33	EF Rate (Hz) at 3e33
		L1	EF		
Single leptons	Single muon > 20GeV	11 GeV	18 GeV	8	100
	Single electron > 25GeV	16 GeV	22 GeV	9	55
Two leptons	2 muons > 17, 12GeV	11GeV	15,10GeV	8	4
	2 electrons, each > 15GeV	2x10GeV	2x12GeV	2	3
	2 taus > 45, 30GeV	15,11GeV	29,20GeV	7.5	15

<b>TOTAL</b>				<75	<b>~400 (mean)</b>

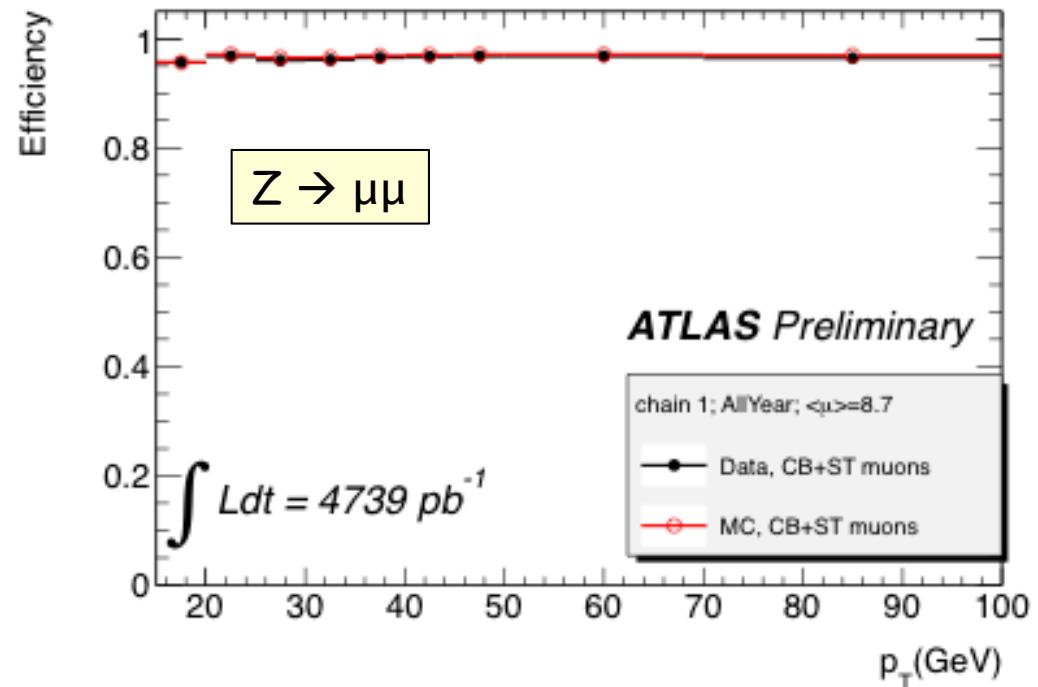

## 2 $\mu$ 2e candidate with $m_{2\mu 2e} = 123.6$ GeV

$p_T(\mu^-, \mu^+, e^-, e^+) = 43.9, 43.5, 11.2, 9.9$  GeV  
 $m(\mu^+ \mu^-) = 89.3$  GeV,  $m(e^+ e^-) = 30$  GeV

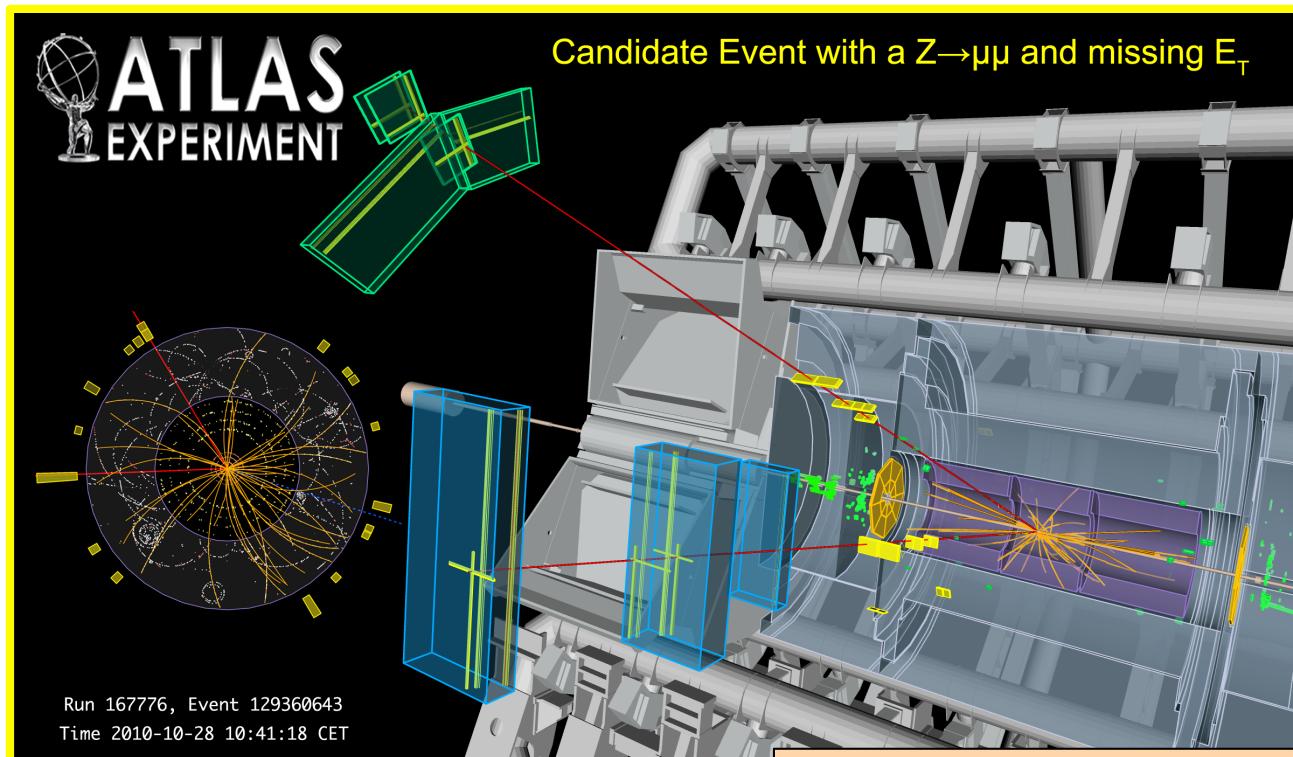

Muon reconstruction efficiency  
from Tag & Probe

$H \rightarrow ZZ \rightarrow llvv$  ( $l=e,\mu$ )

$200 \leq m_H \leq 600$  GeV

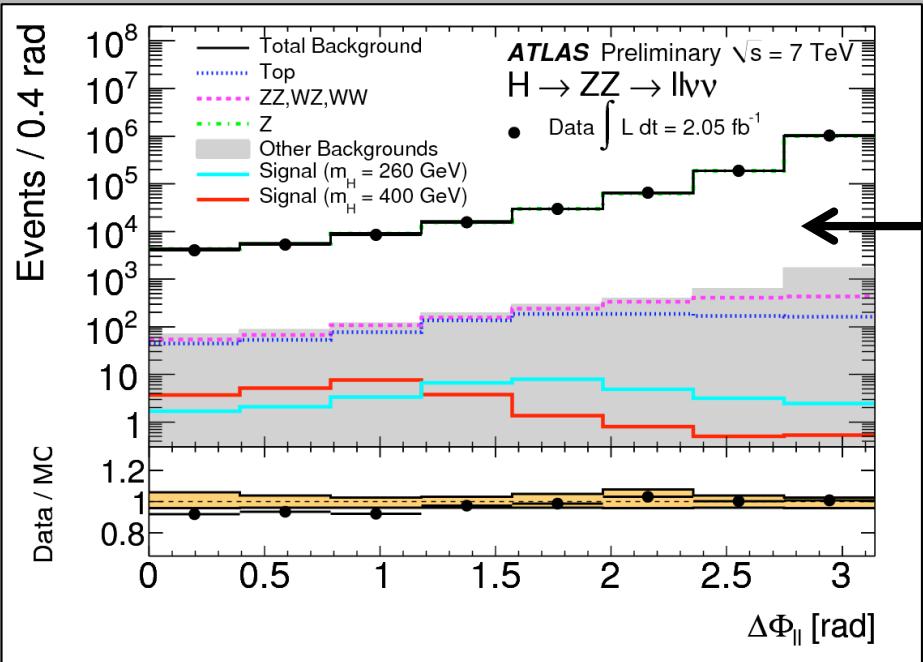

- Larger BR than  $H \rightarrow 4l$ :  $\rightarrow \sigma \sim 20$  fb  
Good S/B  
 $\rightarrow$  most sensitive channel for  $m_H > 300$  GeV
- Signature is  $Z \rightarrow ll + \text{large } E_T^{\text{miss}}$  (both Z's are boosted for large  $m_H$ )
- Main backgrounds:  $ZZ$  (irreducible), top,  $Z+\text{jets}$   
 $\rightarrow$  reject with  $E_T^{\text{miss}}$  cut ( $> 66\text{-}82$  GeV), b-jet veto, topology (small  $\Delta\phi_{ll}$ ,  $m_T$  shape)

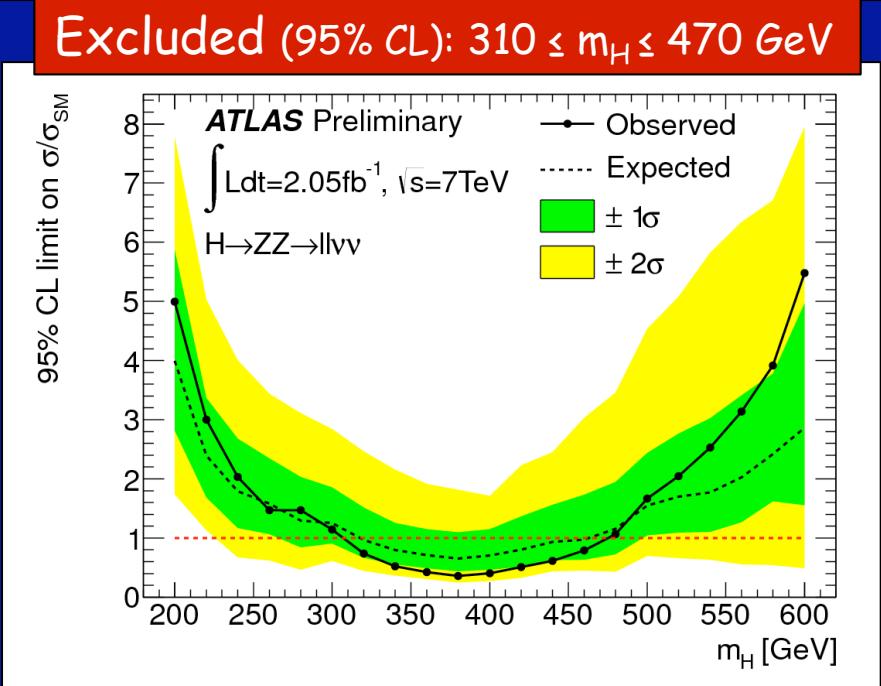

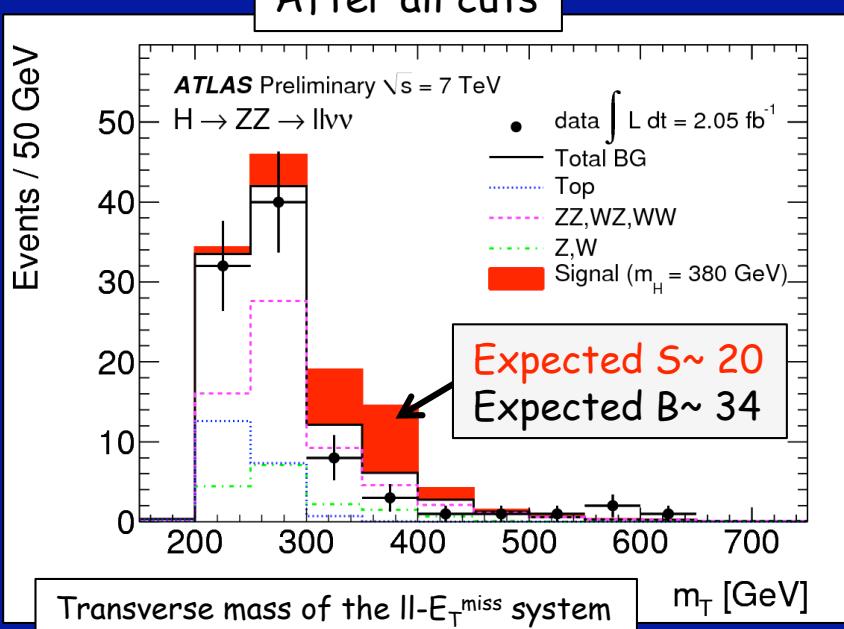

$ZZ \rightarrow \mu\mu vv$  candidate:  
 $m(\mu^+\mu^-) = 93.8$  GeV  
 $p_T(Z) = 156$  GeV  
 $E_T^{\text{miss}} = 161$  GeV

Crucial experimental aspects:

- understand  $E_T^{\text{miss}}$  spectrum, in particular tails from mis-measured jets ( $Z+\text{jets}$  is  $10^5$  larger than signal !)
- understand shape of (irreducible)  $ZZ$  background

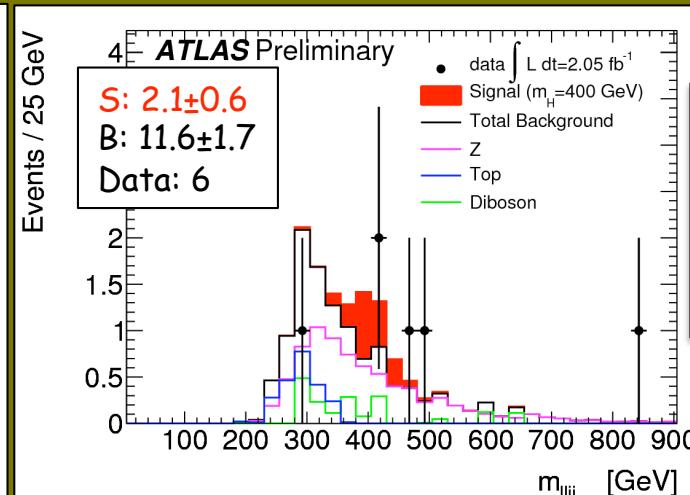

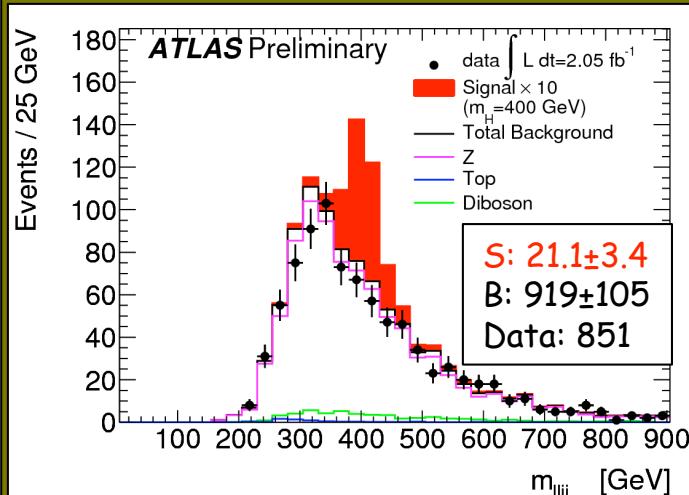

$\Delta\varphi$  between leptons from  $Z \rightarrow ll$  decays  
 $\rightarrow$  exploit to distinguish boosted  $Z$  from  
Higgs decays from  $Z+jets$  and other  
backgrounds

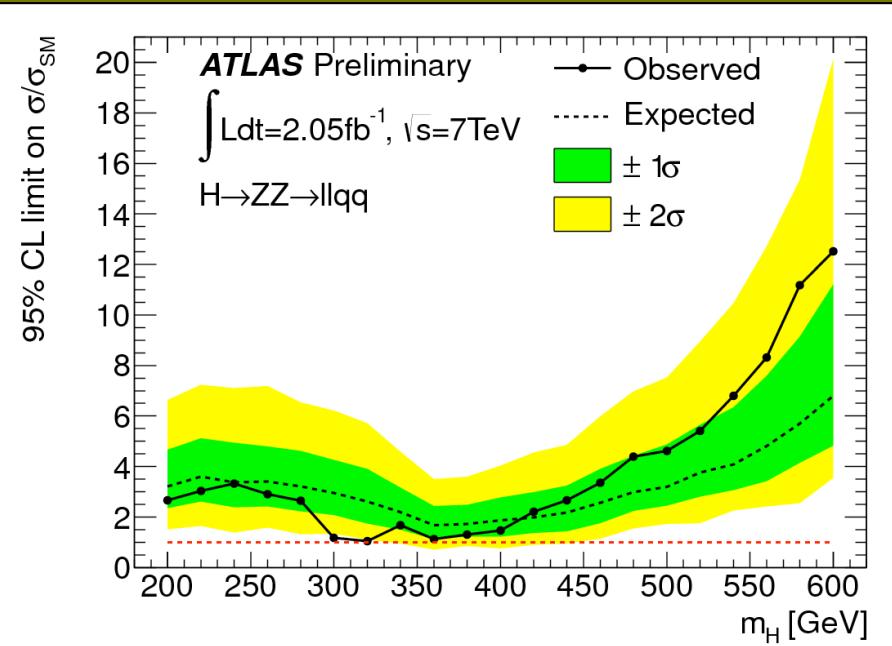

$H \rightarrow ZZ \rightarrow llqq$  ( $l=e,\mu$ )

$200 \leq m_H \leq 600$  GeV

$lljj$  invariant mass for the untagged (left) and b-tagged (right) selections. The Higgs signal in the untagged plot is scaled by  $\times 10$ .

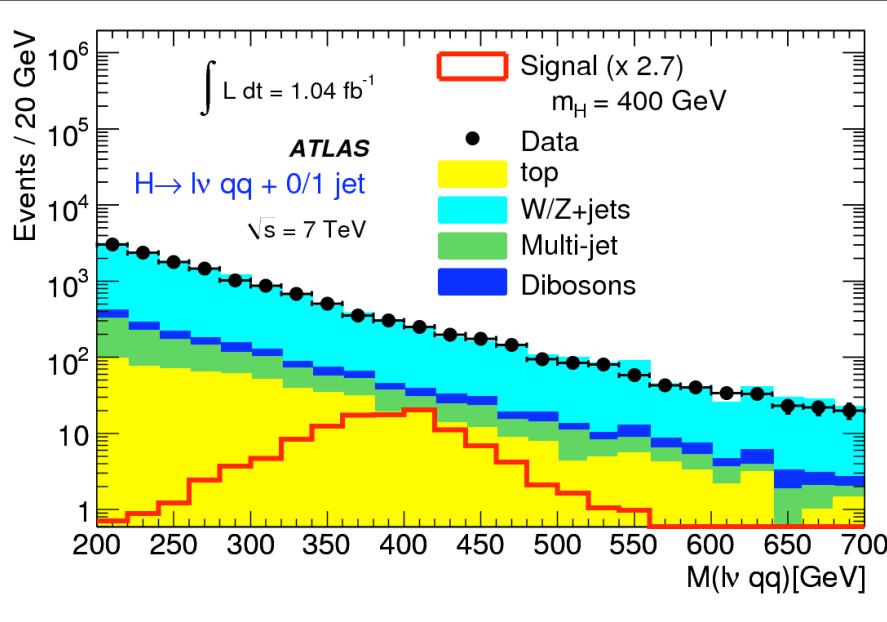

Helpful channel in the Higgs mass range  $m_H > 2m_Z$   
 $\sigma \times BR \sim 10 \text{ fb}$   
Signature:  $Z \rightarrow ll + 2 \text{ jets}$

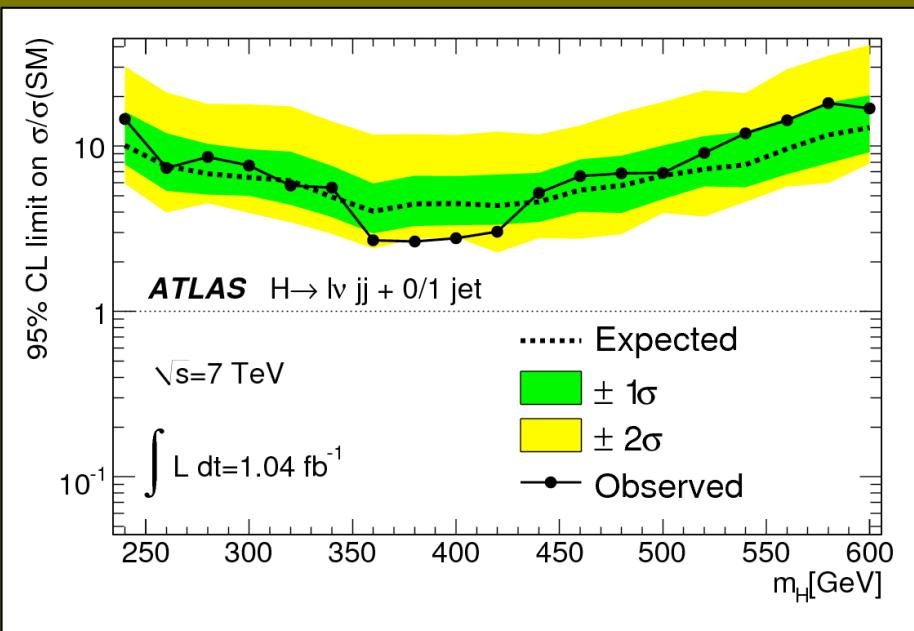

- Reconstruct a  $Z \rightarrow ll$  and a second  $Z \rightarrow jj$
- $E_T^{\text{miss}} < 50$  GeV against top background
- Reconstruct  $m_{lljj}$  (with  $m_{jj}$  scaled to  $m_Z$ )
- $Z + \text{jets}$  background: MC normalised to data in the sidebands of the  $m_{jj}$  distribution
- Sample with b-tagged jets gives  $\times 10$  smaller signal ( $\sim 1$  evt) but  $\times 10$  larger S/B ( $\sim 0.2$ )

# $H \rightarrow WW \rightarrow l\nu qq$ ( $l=e,\mu$ )

$240 \leq m_H \leq 600$  GeV

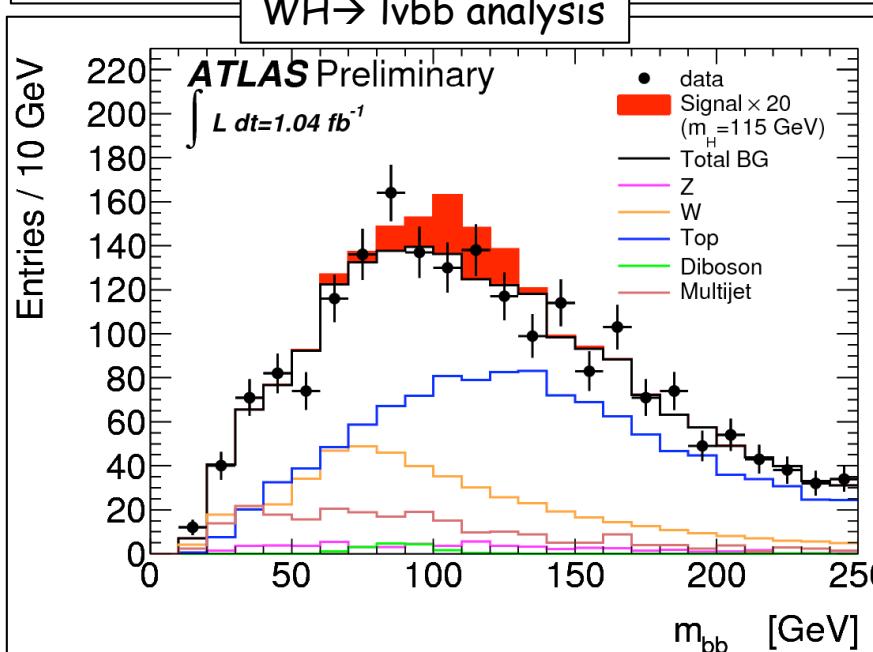

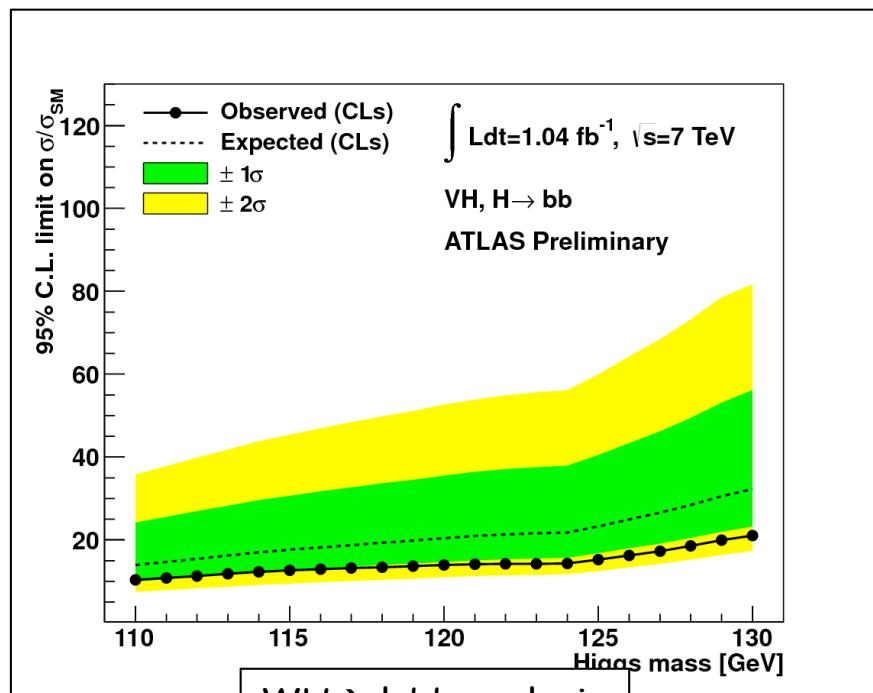

- $\sigma \times \text{BR} \sim 200$  fb
- 1 lepton  $p_T > 30$  GeV,  $E_T^{\text{miss}} > 30$  GeV, 2-3 jets  $p_T > 25$  GeV, no b-tagged jets
- $m_{jj}$  compatible with  $m_W$ , constrain  $m_{l\nu} = m_W$
- fit  $m_{l\nu jj}$  mass spectrum with exponential function plus expected signal
- W+jets and multijet background from data (control samples with relaxed lepton identification or low  $E_T^{\text{miss}}$ ), though not needed for limits extraction

Data: 22161 events  
Expected background: 22630 events  
Expected signal ( $m_H=400$  GeV):  $43 \pm 12$  events

# WH $\rightarrow$ l $v$ bb, ZH $\rightarrow$ ll bb (l=e, $\mu$ )

110  $\leq m_H \leq 130 \text{ GeV}$

WH  $\rightarrow$  lvbb

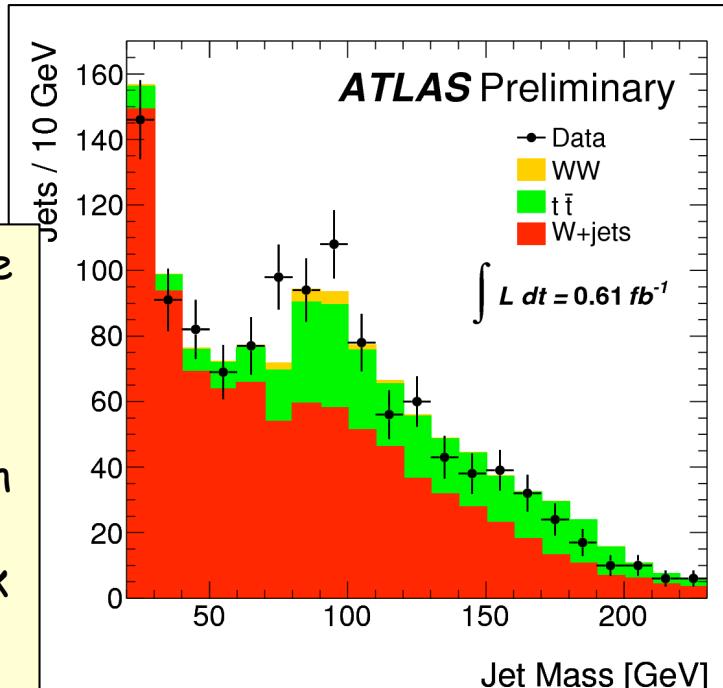

- ◻  $\sigma \times \text{BR} \sim 80 \text{ fb}$
- ◻ 1 lepton  $p_T > 25 \text{ GeV}, E_T^{\text{miss}} > 25 \text{ GeV}, m_T(lv) > 40 \text{ GeV}$ , 2 b-tagged jets, no other jets
- ◻ Main backgrounds: Wbb, top

ZH  $\rightarrow$  llbb

- ◻  $\sigma \times \text{BR} \sim 15 \text{ fb}$
- ◻ 2 leptons  $p_T > 20 \text{ GeV}, m_{ll} \sim m_Z, E_T^{\text{miss}} < 50 \text{ GeV}$ , 2 b-tagged jets
- ◻ Main backgrounds: Zbb, top

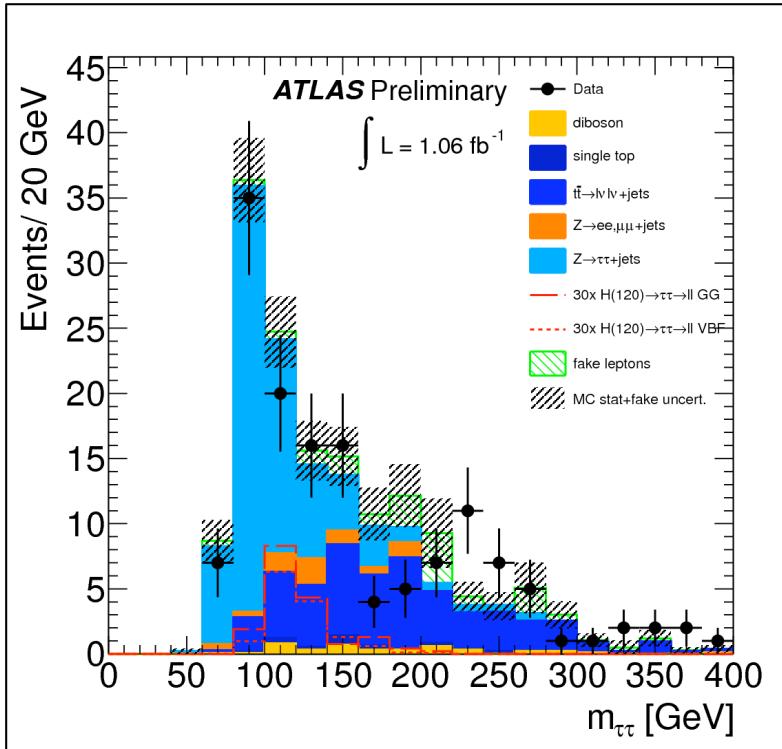

Backgrounds: from data (mainly from sidebands of  $m_{bb}$  distribution)

"Engineering" the boosted H  $\rightarrow$  bb technique: jet mass in events with W  $\rightarrow$  lv with  $p_T > 200 \text{ GeV}$   
Clear W  $\rightarrow$  jj peak from top events visible

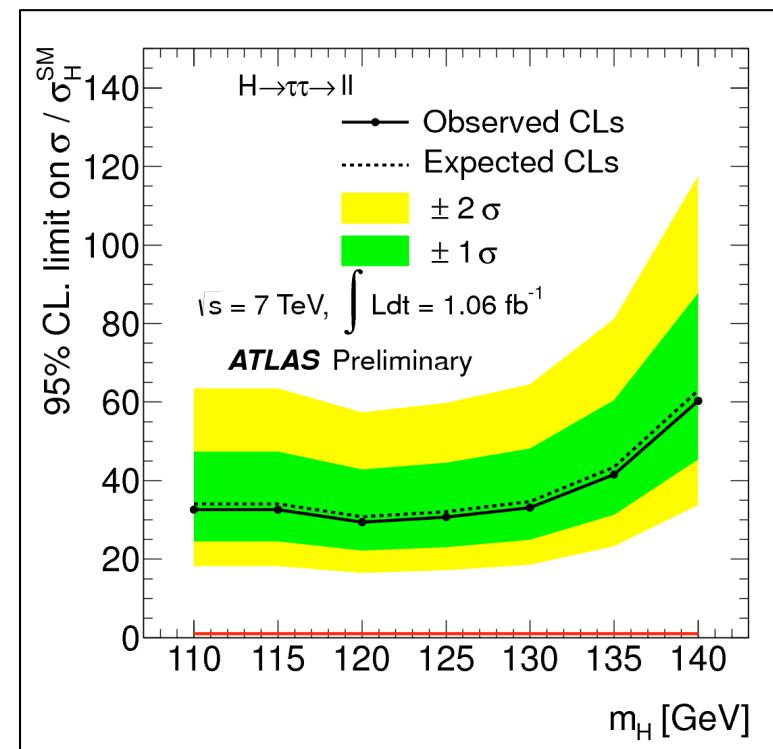

# $H \rightarrow \tau\tau \rightarrow ll + \text{neutrinos} (l=e,\mu)$

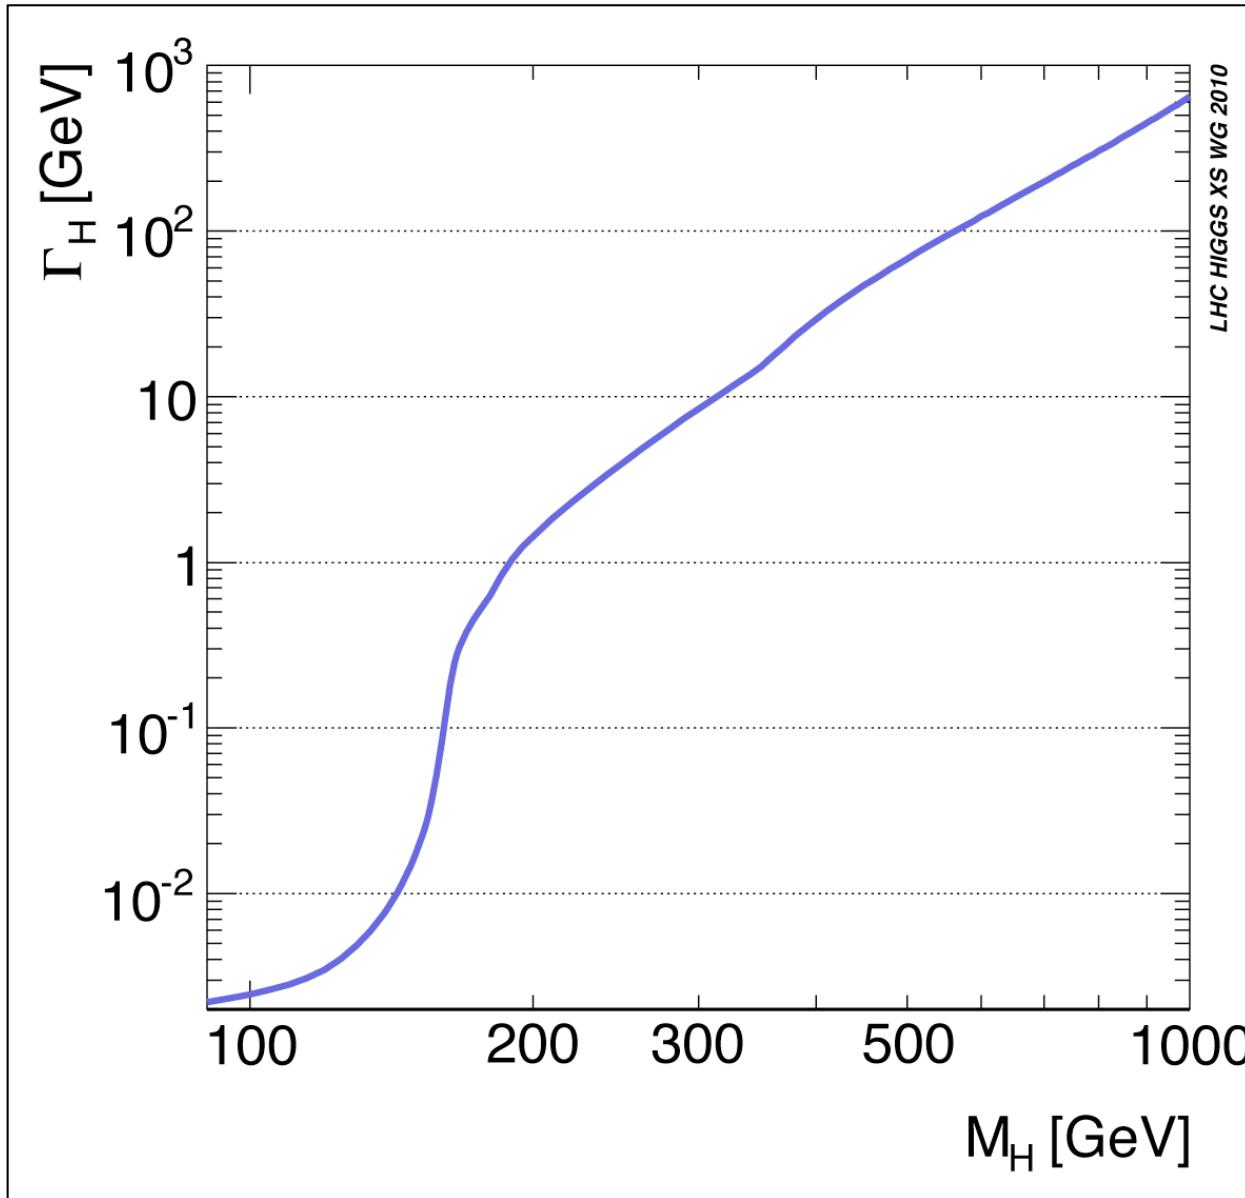

$110 \leq m_H \leq 140 \text{ GeV}$

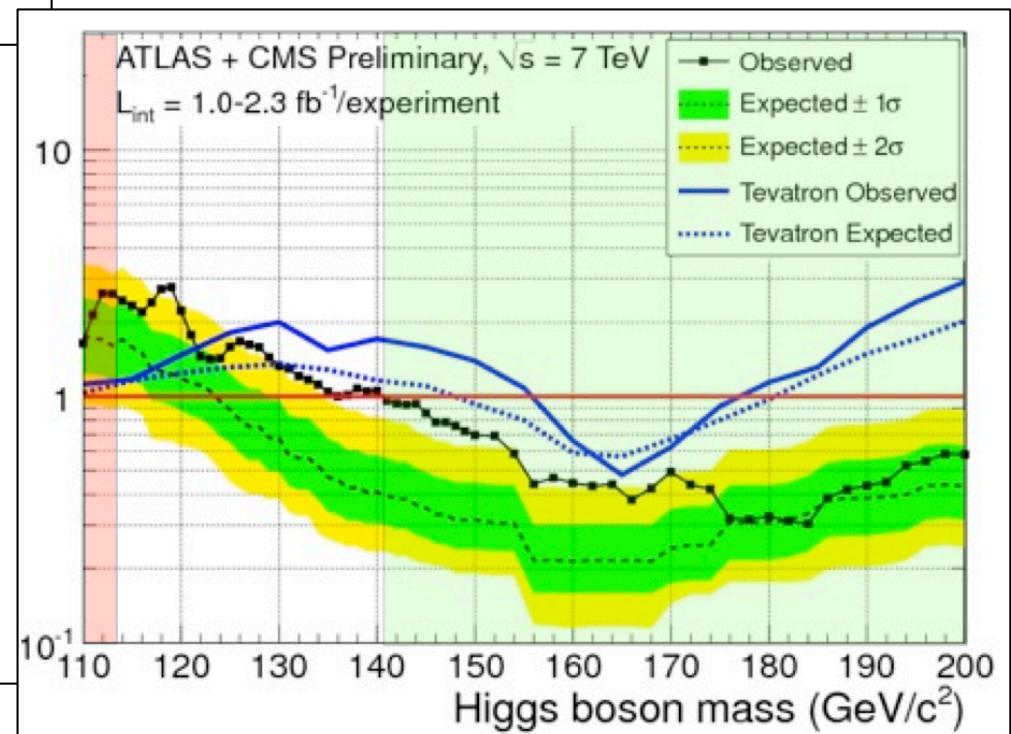

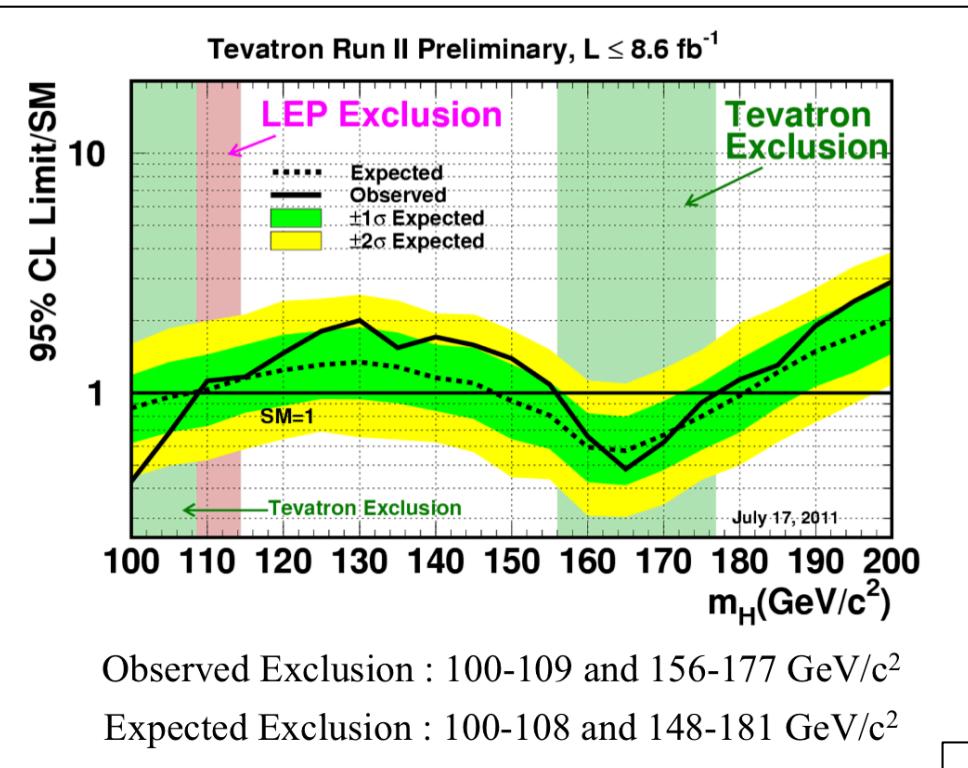

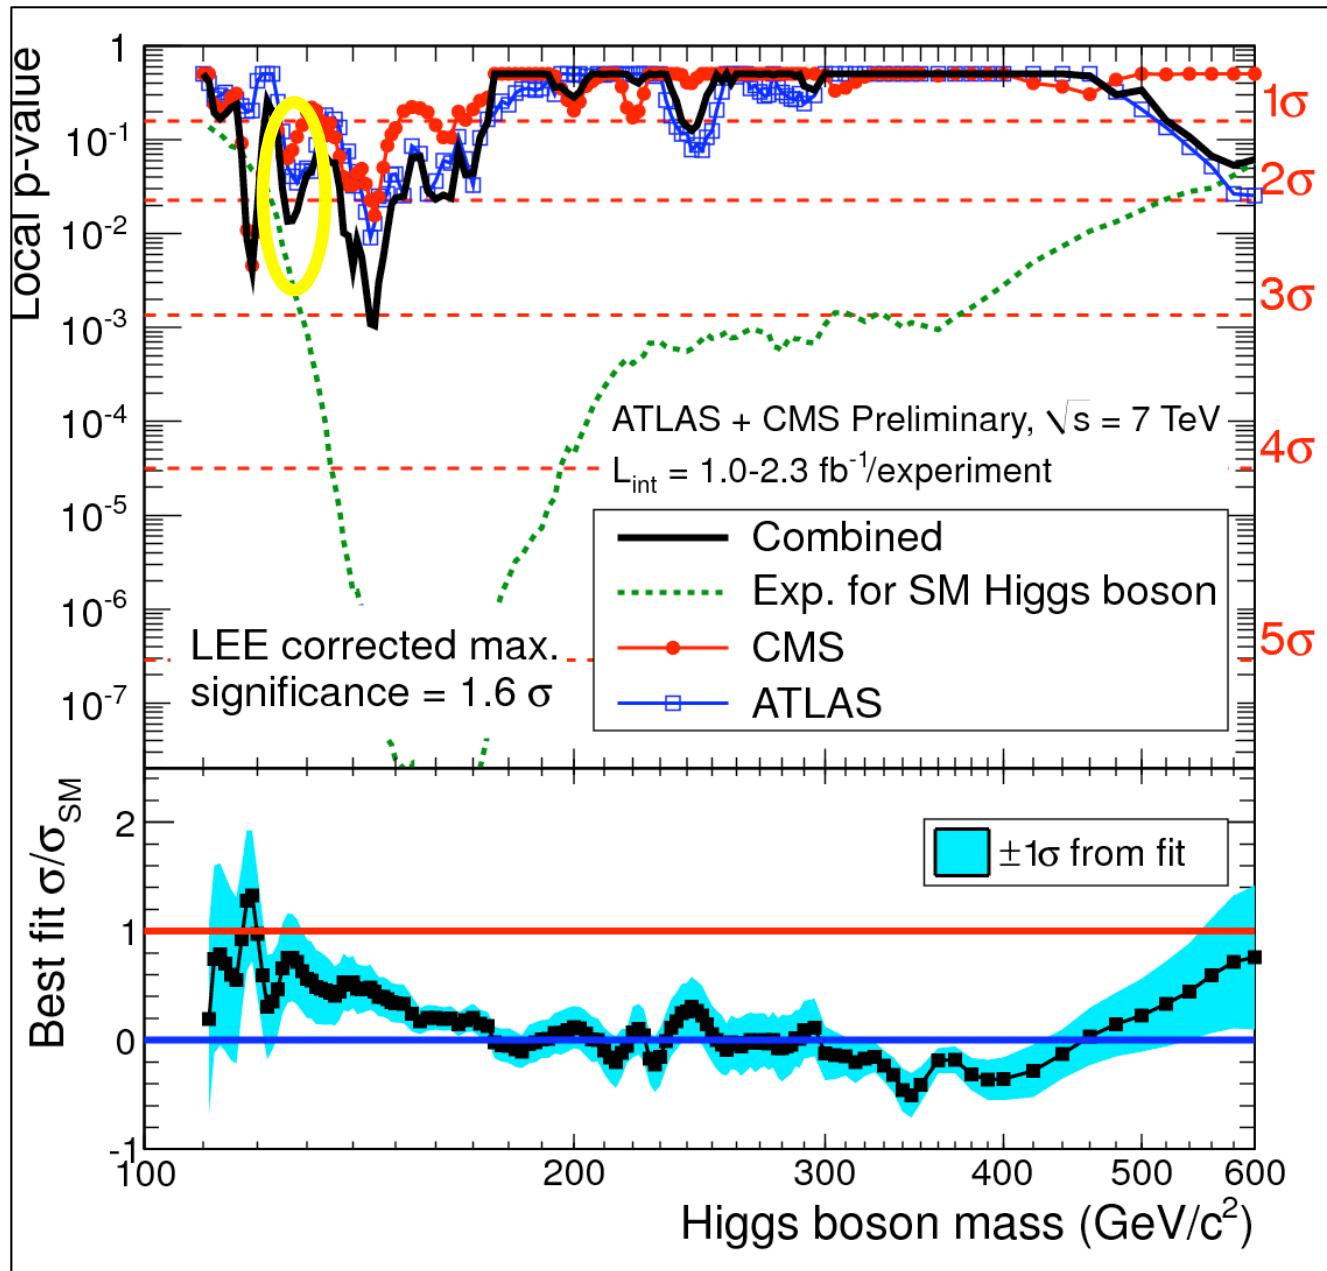

- $\sigma \times \text{BR} \sim 150 \text{ fb}$
- $p_T(l) > 15-10 \text{ GeV}, E_T^{\text{miss}} > 25-30 \text{ GeV}, p_T(\text{jet}) > 40 \text{ GeV}$  (enhances S/B), topological cuts
- $m_{\tau\tau}$  from collinear approximation: 100-150 GeV
- Main backgrounds:  $Z \rightarrow \tau\tau$ , top  $Z \rightarrow \tau\tau$  from replacing  $\mu$  in  $Z \rightarrow \mu\mu$  events with simulated  $\tau$

	Events
Observed	<b>46</b>

$gg \rightarrow H(120 \text{ GeV})$	<b><math>0.44 \pm 0.05</math></b>
VBF $H(120 \text{ GeV})$	<b><math>0.38 \pm 0.02</math></b>

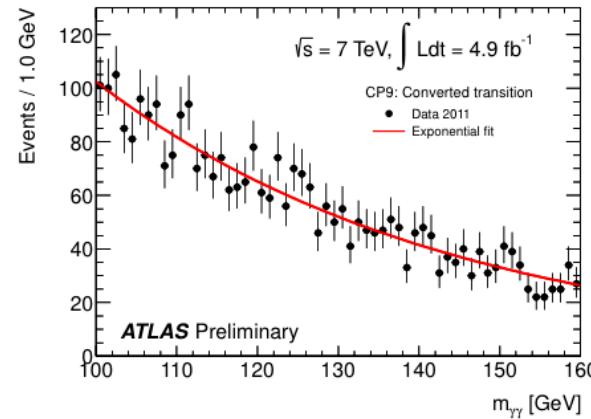

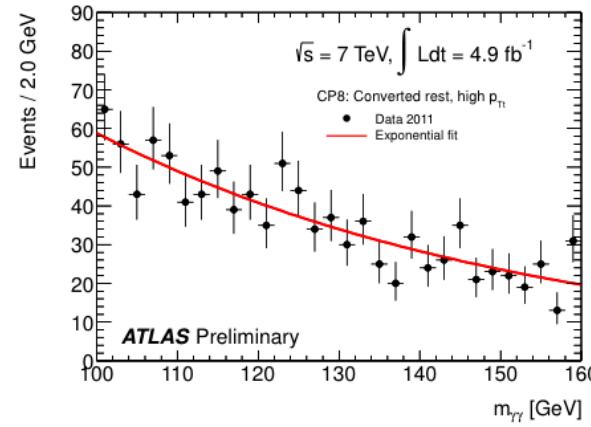

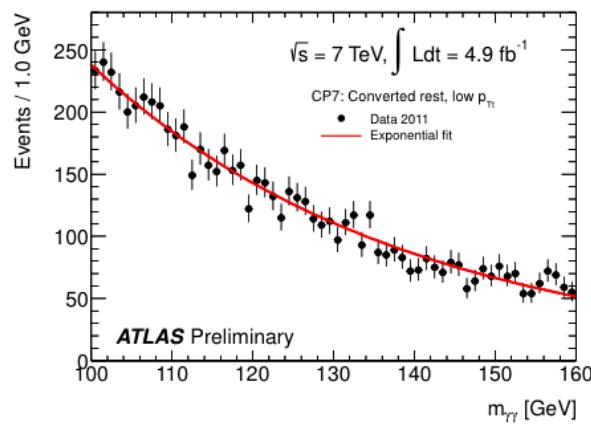

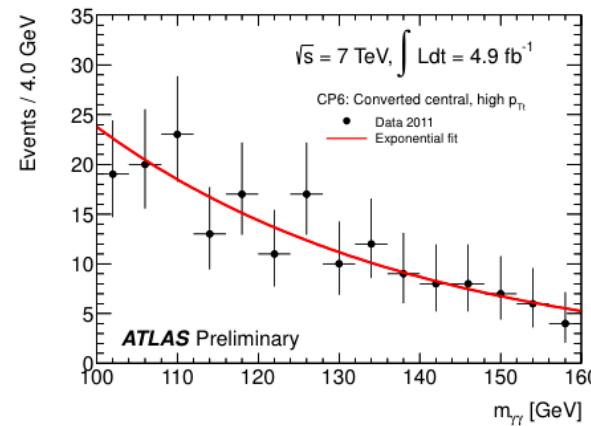

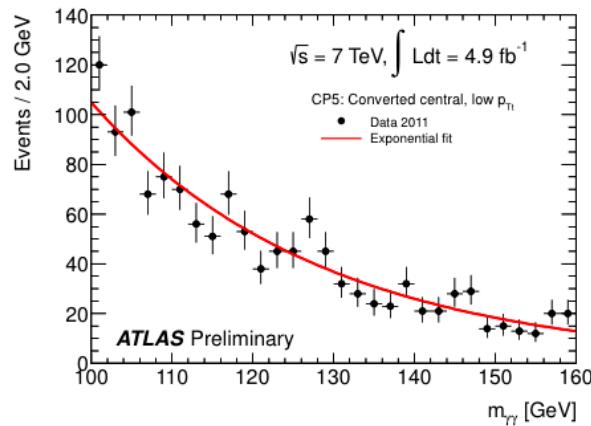

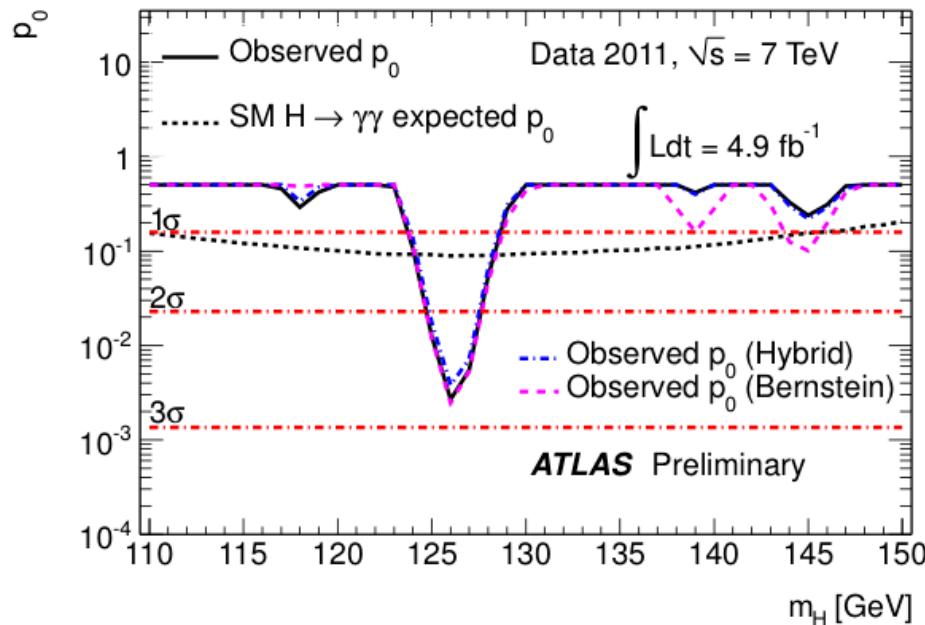

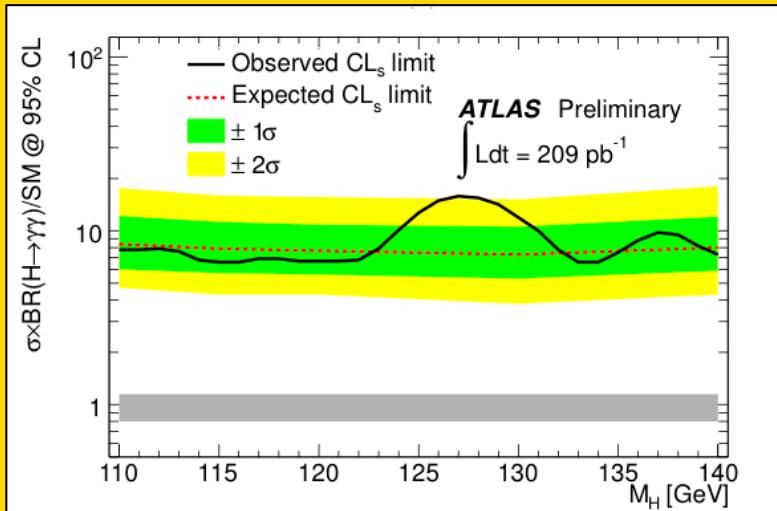

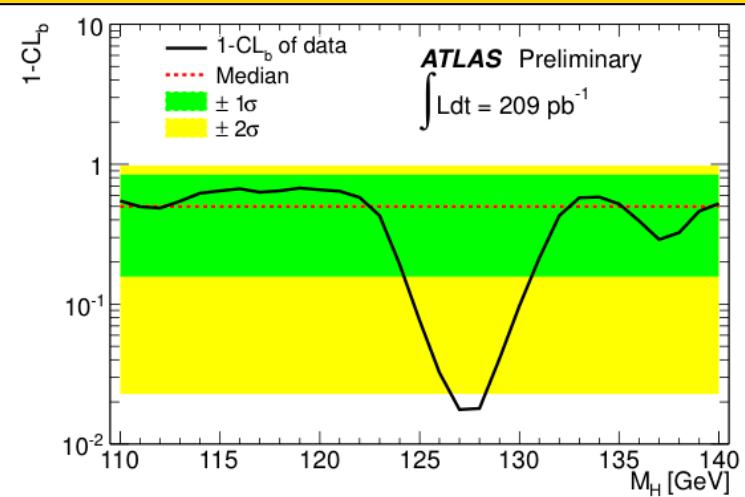

Figure 12: The observed and expected local  $p_0$ -value as a function of  $m_H$  for three different background models without taking the *look-elsewhere effect* into account. The black solid line is the result described in detail in this note, using single exponential functions in all categories. In the *Hybrid* model the high  $p_{\text{Ti}}$  categories are fitted with the 2<sup>nd</sup> order Bernstein polynomials, the other categories with the single exponential. In the model *Bernstein* all categories are fitted with the Bernstein function. The  $p_0$ -values near the minima at 126 GeV are very similar in all cases:  $p_0=0.38\%$  using the *Hybrid* model, and  $p_0=0.25\%$  using the *Bernestein* function.

June 2011: PLHC conference

July 2011: EPS conference

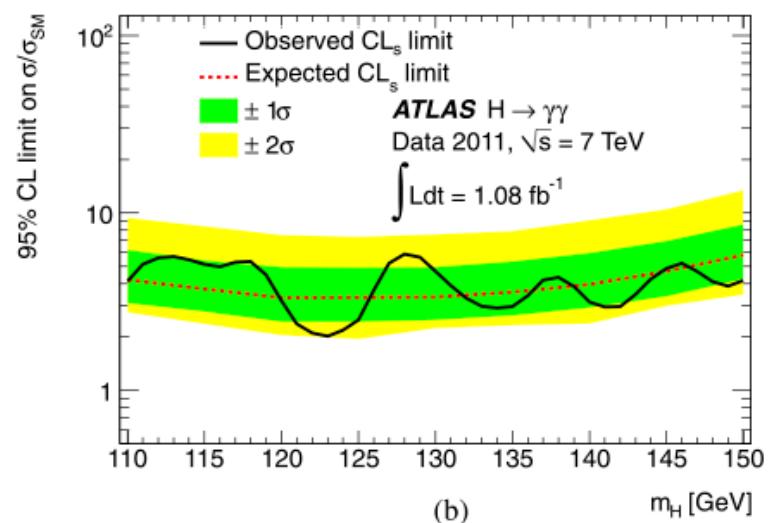

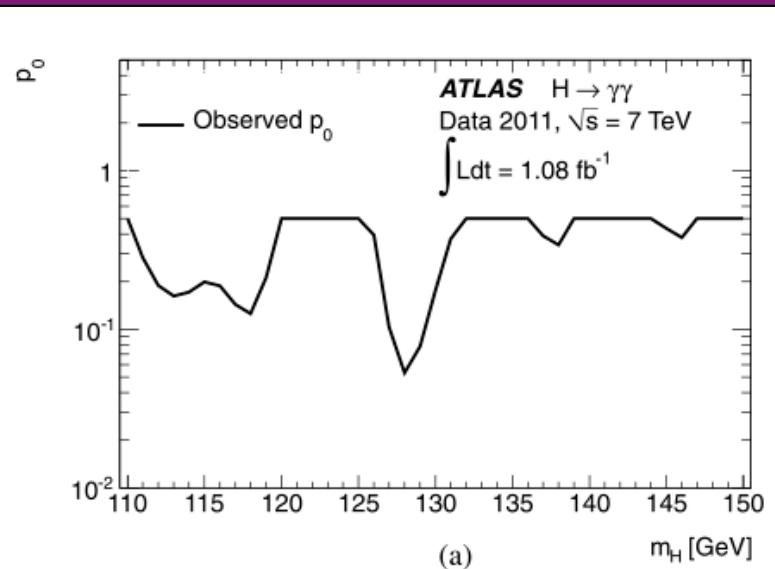

Table 5: Systematic uncertainty on the background modelling in different categories.

Category	CP1	CP2	CP3	CP4	CP5	CP6	CP7	CP8	CP9
Events	$\pm 4.3$	$\pm 0.2$	$\pm 3.7$	$\pm 0.5$	$\pm 3.2$	$\pm 0.1$	$\pm 5.6$	$\pm 0.6$	$\pm 2.3$

Table 3: Expected Higgs boson signal yields in  $4.9 \text{ fb}^{-1}$  integrated over a mass range of 100-160 GeV for various values of  $m_H$  in each category and the sum.

$m_H$ [GeV]	110	115	120	125	130	135	140	145	150
CP1: Unconverted Central, low $p_{\text{T}t}$	8.9	8.9	8.7	8.2	7.5	6.7	5.7	4.6	3.5
CP2: Unconverted Central, high $p_{\text{T}t}$	2.5	2.6	2.6	2.5	2.3	2.1	1.8	1.5	1.2
CP3: Unconverted Rest, low $p_{\text{T}t}$	16.3	16.7	16.6	16.0	15.0	13.6	11.9	9.8	7.4
CP4: Unconverted Rest, high $p_{\text{T}t}$	4.4	4.6	4.6	4.5	4.3	4.0	3.5	2.9	2.2
CP5: Converted Central, low $p_{\text{T}t}$	5.9	5.9	5.8	5.5	5.1	4.6	4.0	3.3	2.4
CP6: Converted Central, high $p_{\text{T}t}$	1.6	1.7	1.6	1.6	1.6	1.4	1.3	1.1	0.8

Total	69.9	71.5	70.9	68.3	63.7	57.5	49.8	40.8	30.6

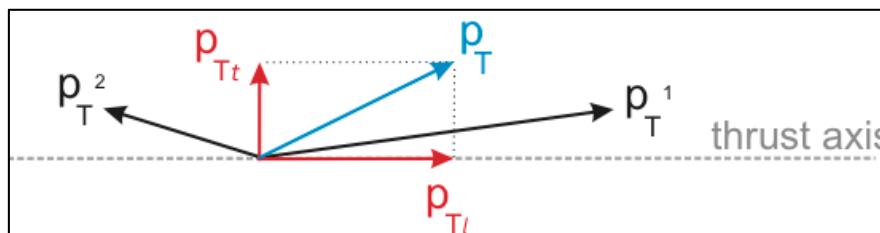

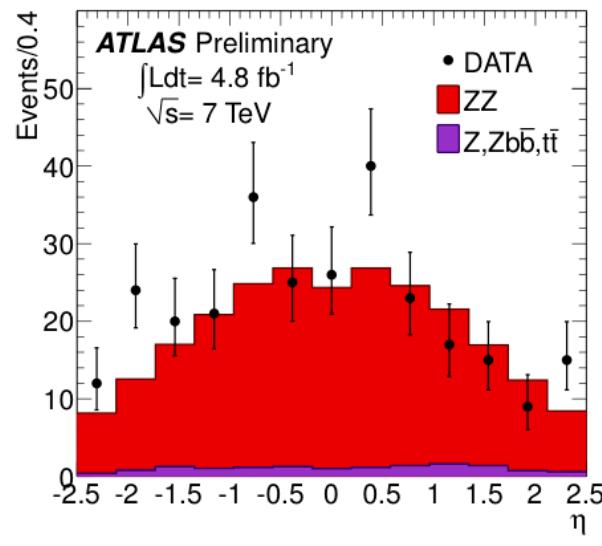

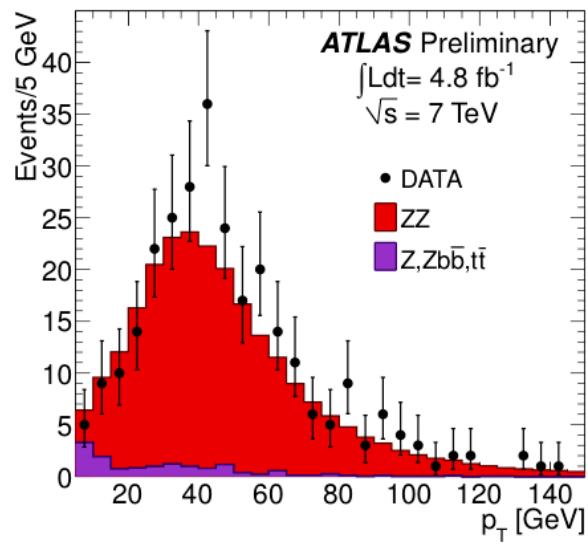

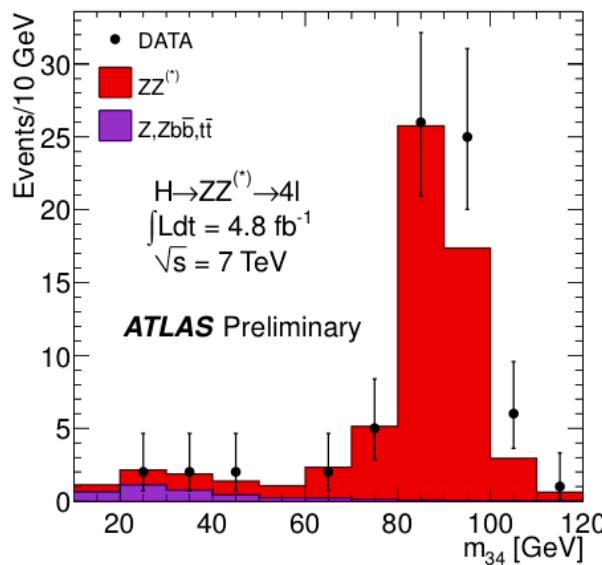

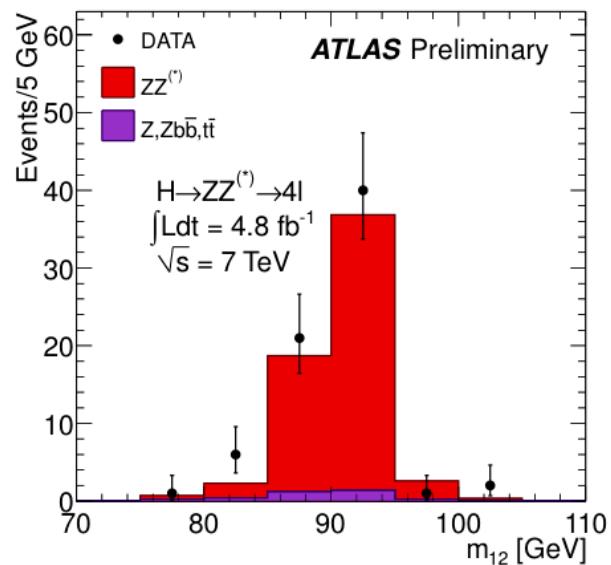

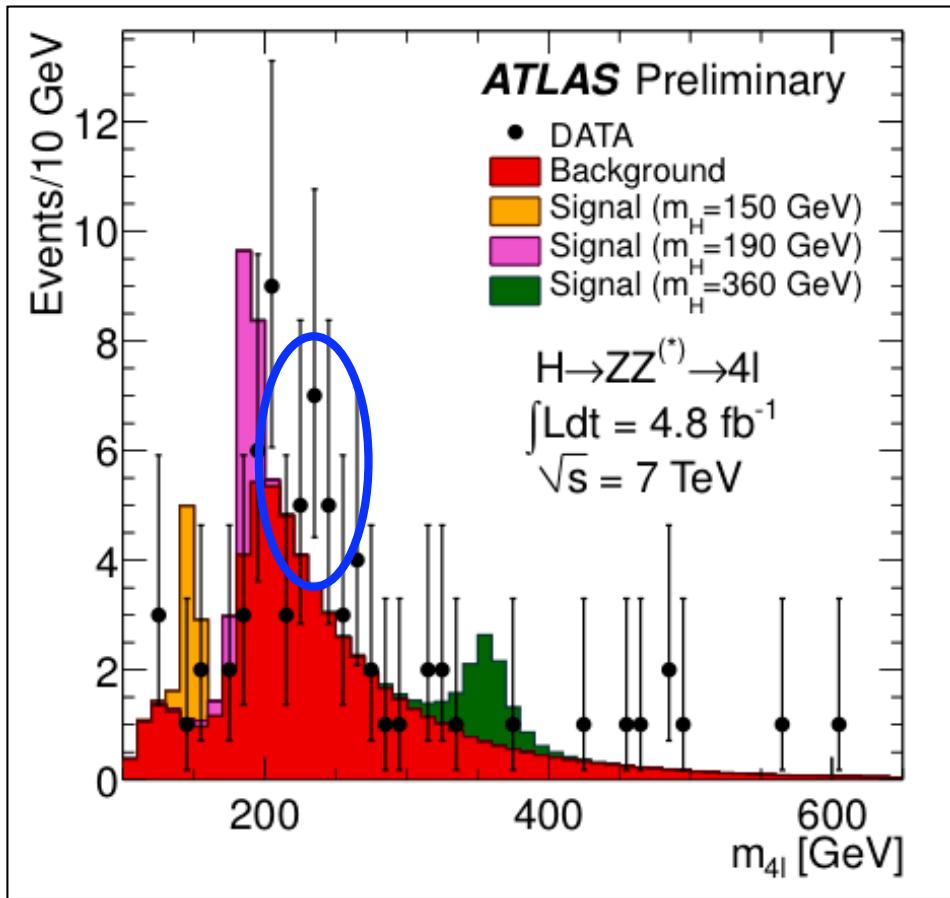

Table 2: The number of events found in  $4.9 \text{ fb}^{-1}$  of data for the nine categories.

Category	Conversion and $\eta$	$p_{\text{Tt}}$ cut	Number of data events
CP1	Unconverted Central	$p_{\text{Tt}} \leq 40 \text{ GeV}$	1763
CP2	Unconverted Central	$p_{\text{Tt}} > 40 \text{ GeV}$	235
CP3	Unconverted Rest	$p_{\text{Tt}} \leq 40 \text{ GeV}$	6234
CP4	Unconverted Rest	$p_{\text{Tt}} > 40 \text{ GeV}$	1006
CP5	Converted Central	$p_{\text{Tt}} \leq 40 \text{ GeV}$	1318
CP6	Converted Central	$p_{\text{Tt}} > 40 \text{ GeV}$	184
CP7	Converted Rest	$p_{\text{Tt}} \leq 40 \text{ GeV}$	7311
CP8	Converted Rest	$p_{\text{Tt}} > 40 \text{ GeV}$	1072
CP9	Converted Transition	No cut	3366
Total			22489

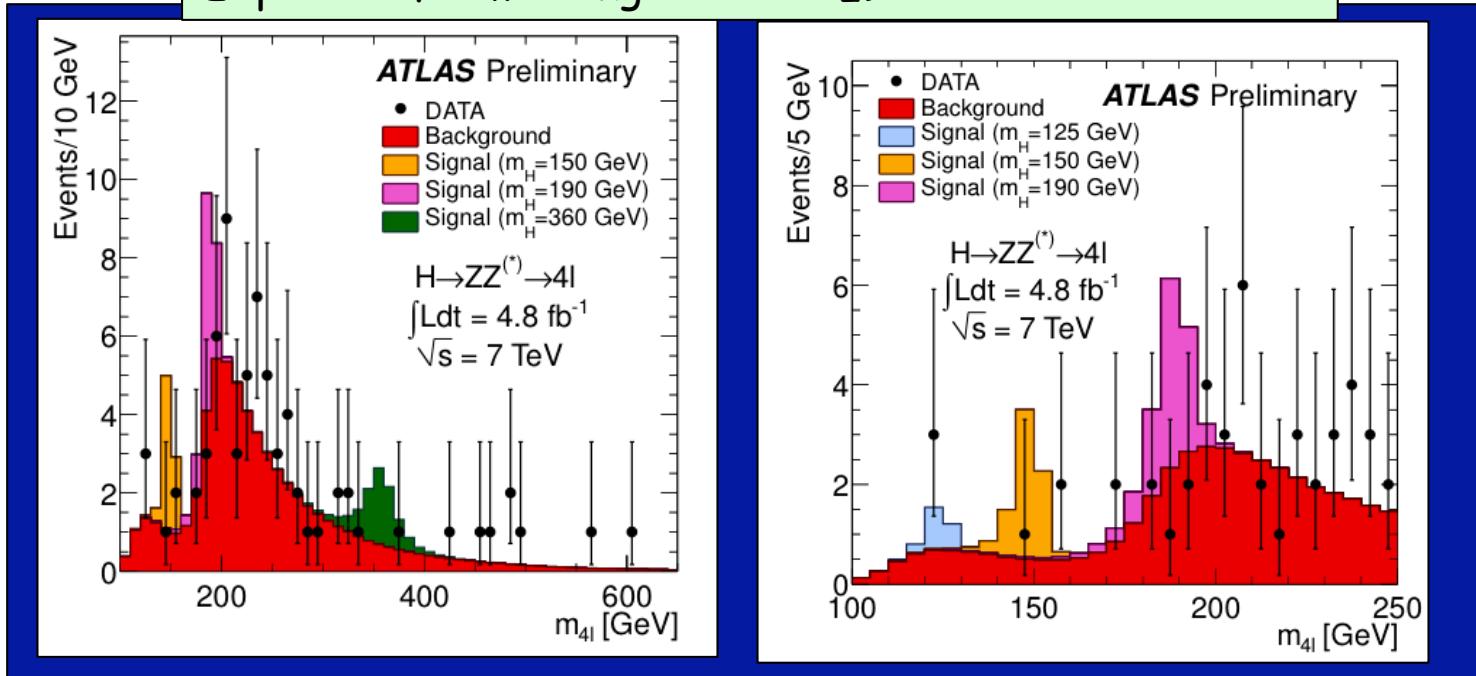

In the region  $212\text{-}255.5 \text{ GeV}$ , containing  $\sim 90\%$  of the signal for  $m_H=244 \text{ GeV}$ , 22 events are observed in the data, with a background expectation of 16 events. The signal expectation is 11 events.

After all selections: kinematic cuts, isolation, impact parameter

Observed in data: 71 events: 24 4 $\mu$  + 30 2e2 $\mu$  + 17 4e  
 Expected from background: 62±9

In the region  $m_H < 141$  GeV (not already excluded at 95% C.L.) 3 events are observed:  
 two 2e2 $\mu$  events ( $m=123.6$  GeV,  $m=124.3$  GeV) and one 4 $\mu$  event ( $m=124.6$  GeV)

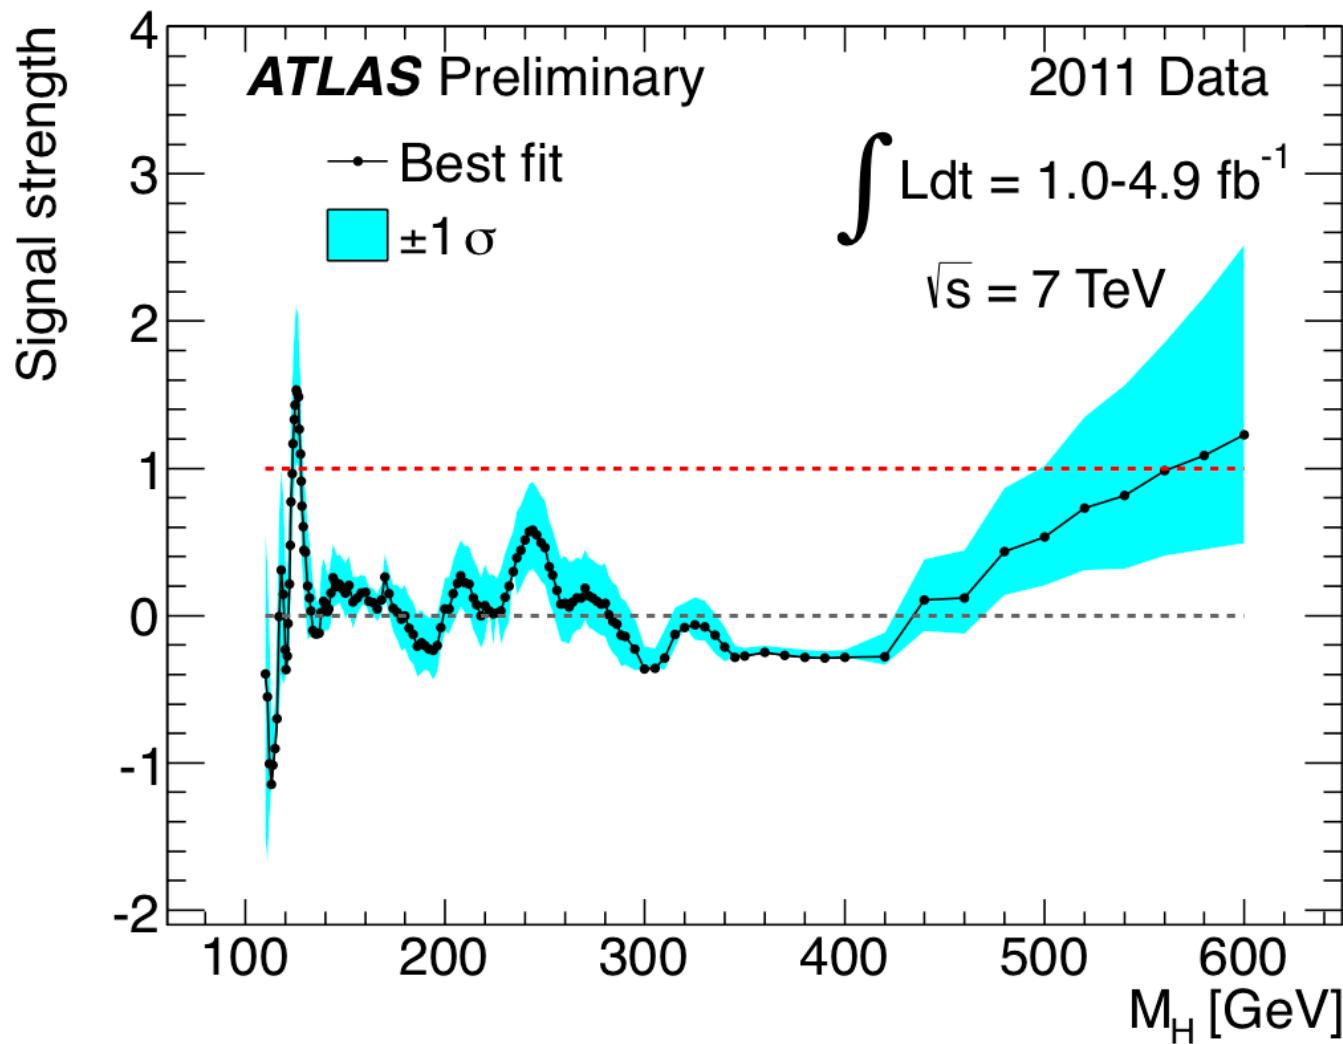

In the region  $117 < m_{4l} < 128$  GeV (containing ~90% of a  $m_H=125$  GeV signal) expect:

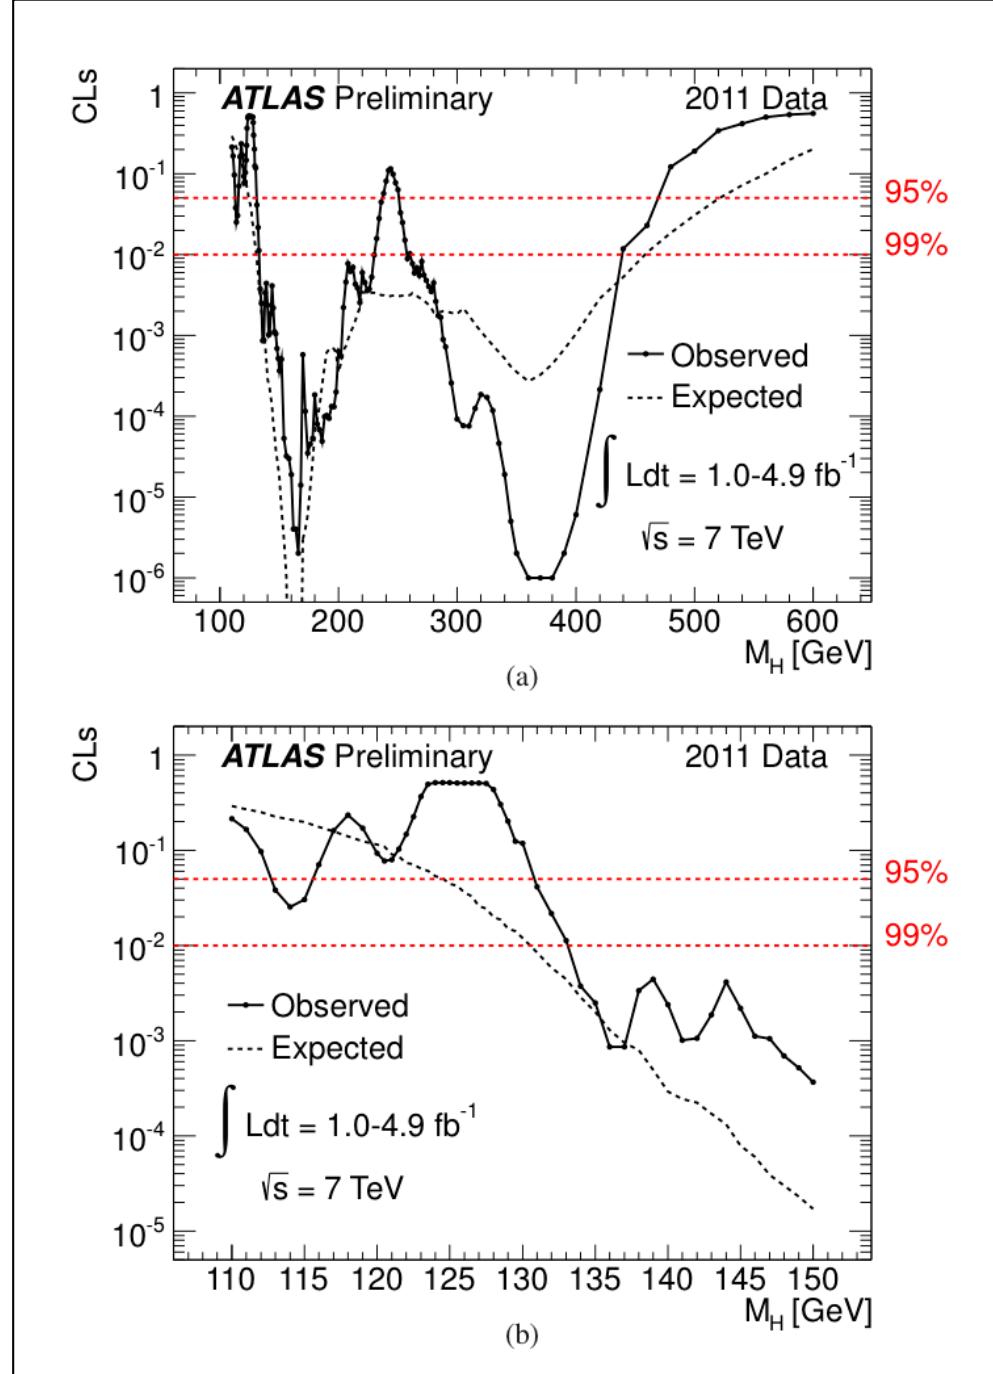

~1.5 events background: 0.26 4 $\mu$  + 0.86 2e2 $\mu$  + 0.64 4e  
 ~1.4 events signal: 0.53 4 $\mu$  + 0.66 2e2 $\mu$  + 0.23 4e

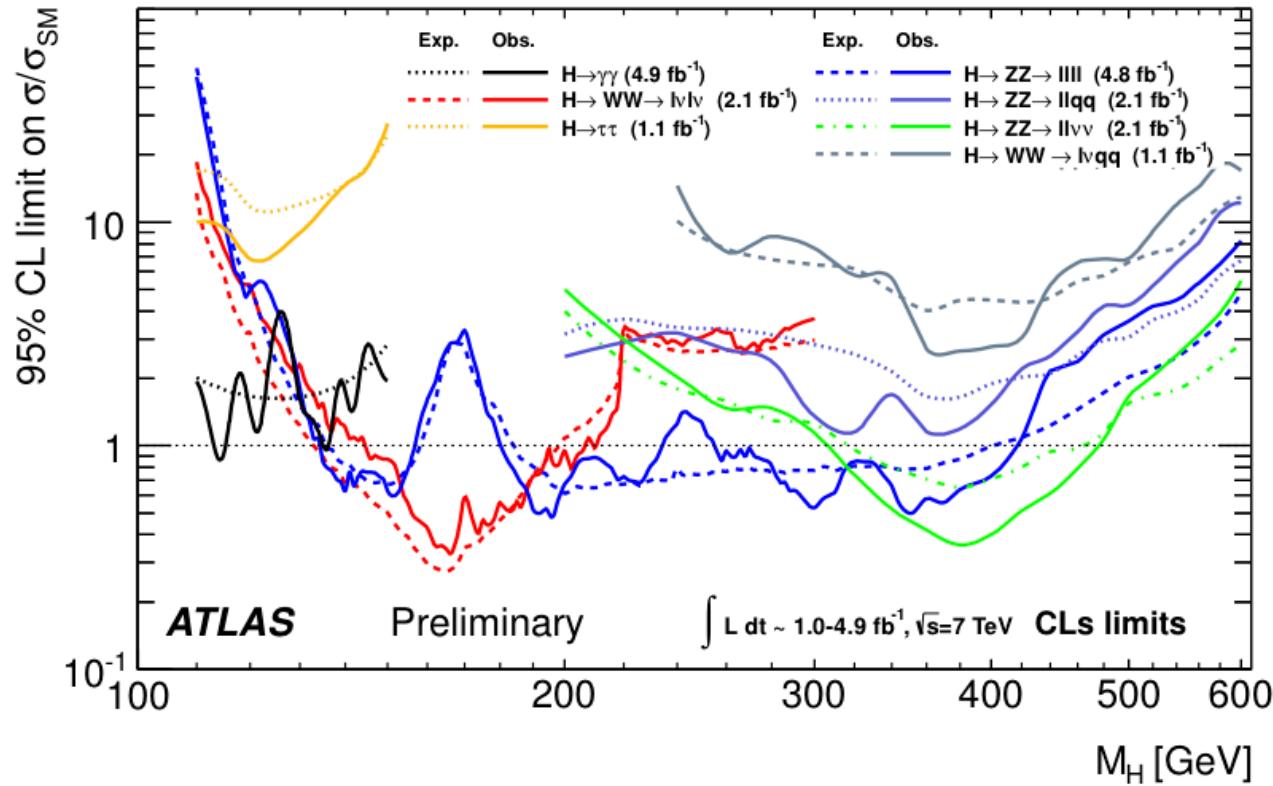

Background dominated by  $ZZ^*$  (4 $\mu$  and 2e2 $\mu$ ),  
 $ZZ^*$  and Z+jets (4e)

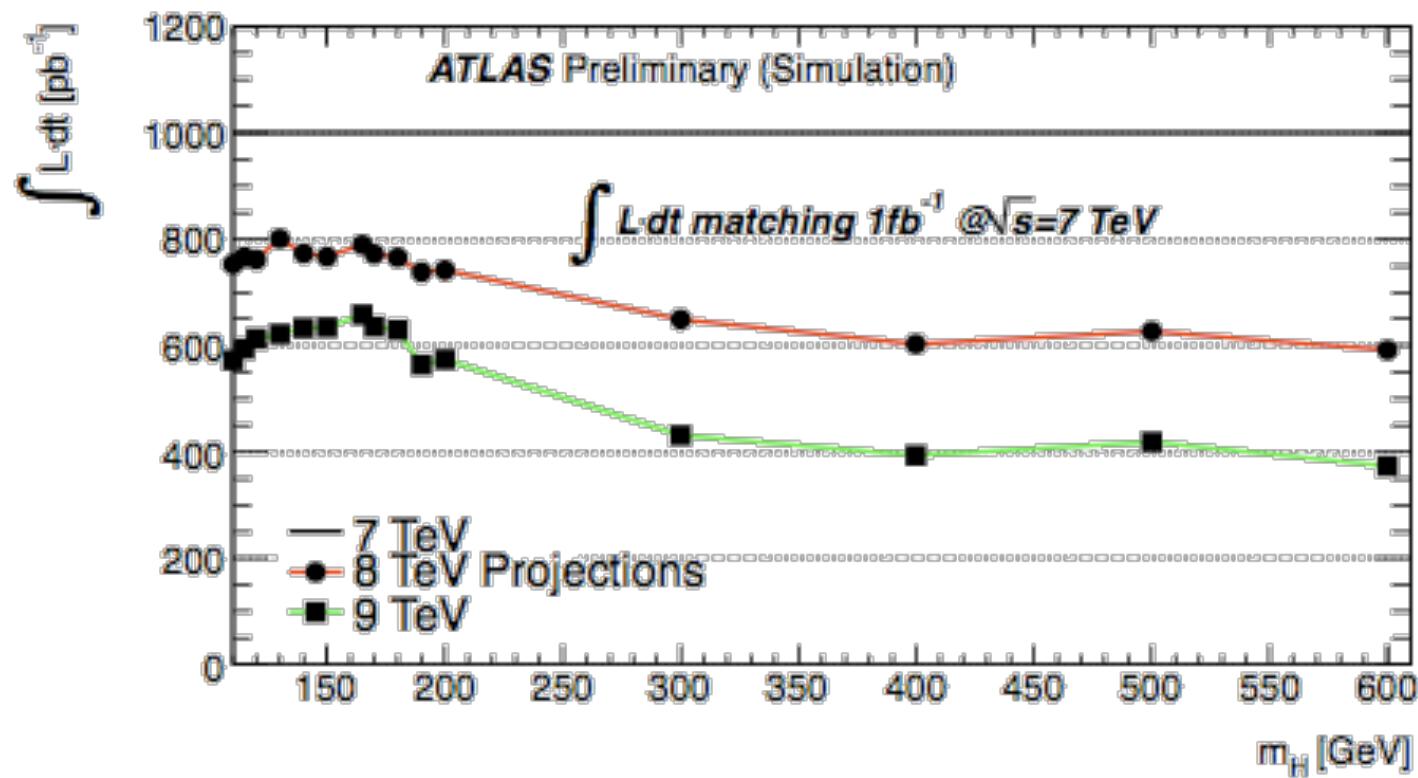

### Main systematic uncertainties

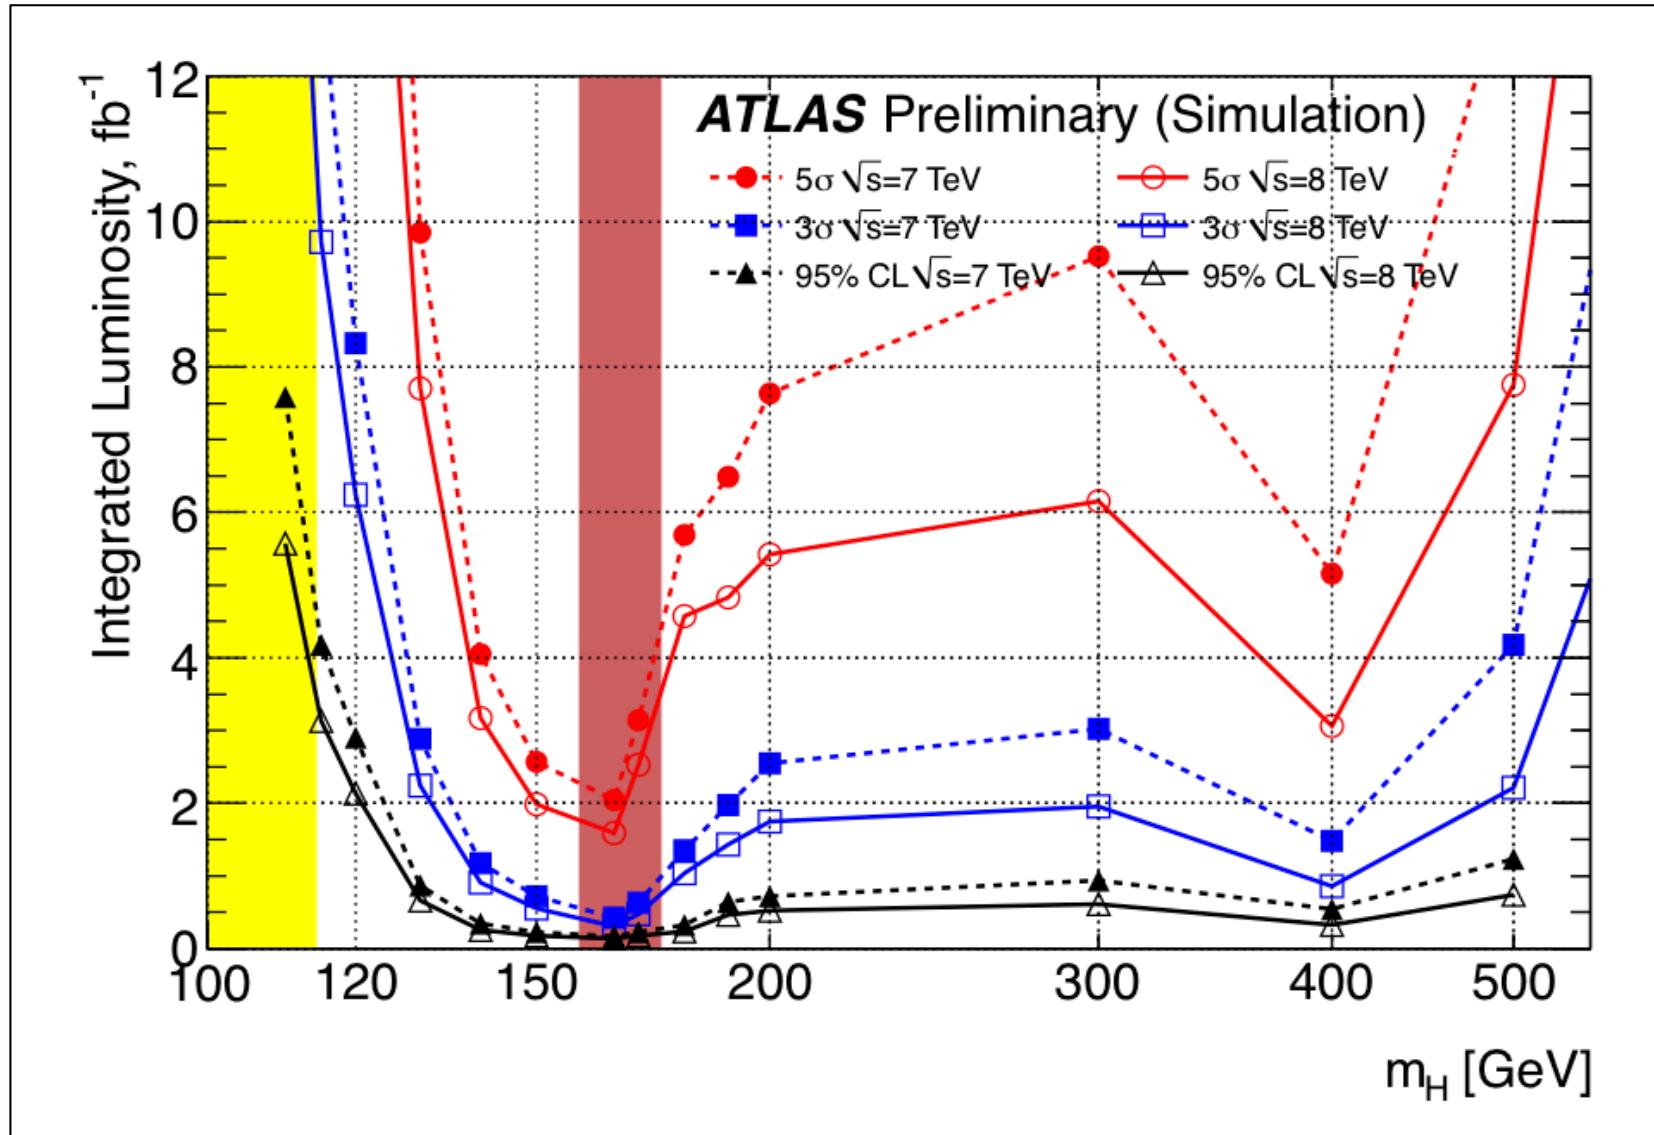

Higgs cross-section	: ~ 15%
Electron efficiency	: ~ 2-8%
Zbb, +jets backgrounds	: ~ 40%
$ZZ^*$ background	: ~ 15%

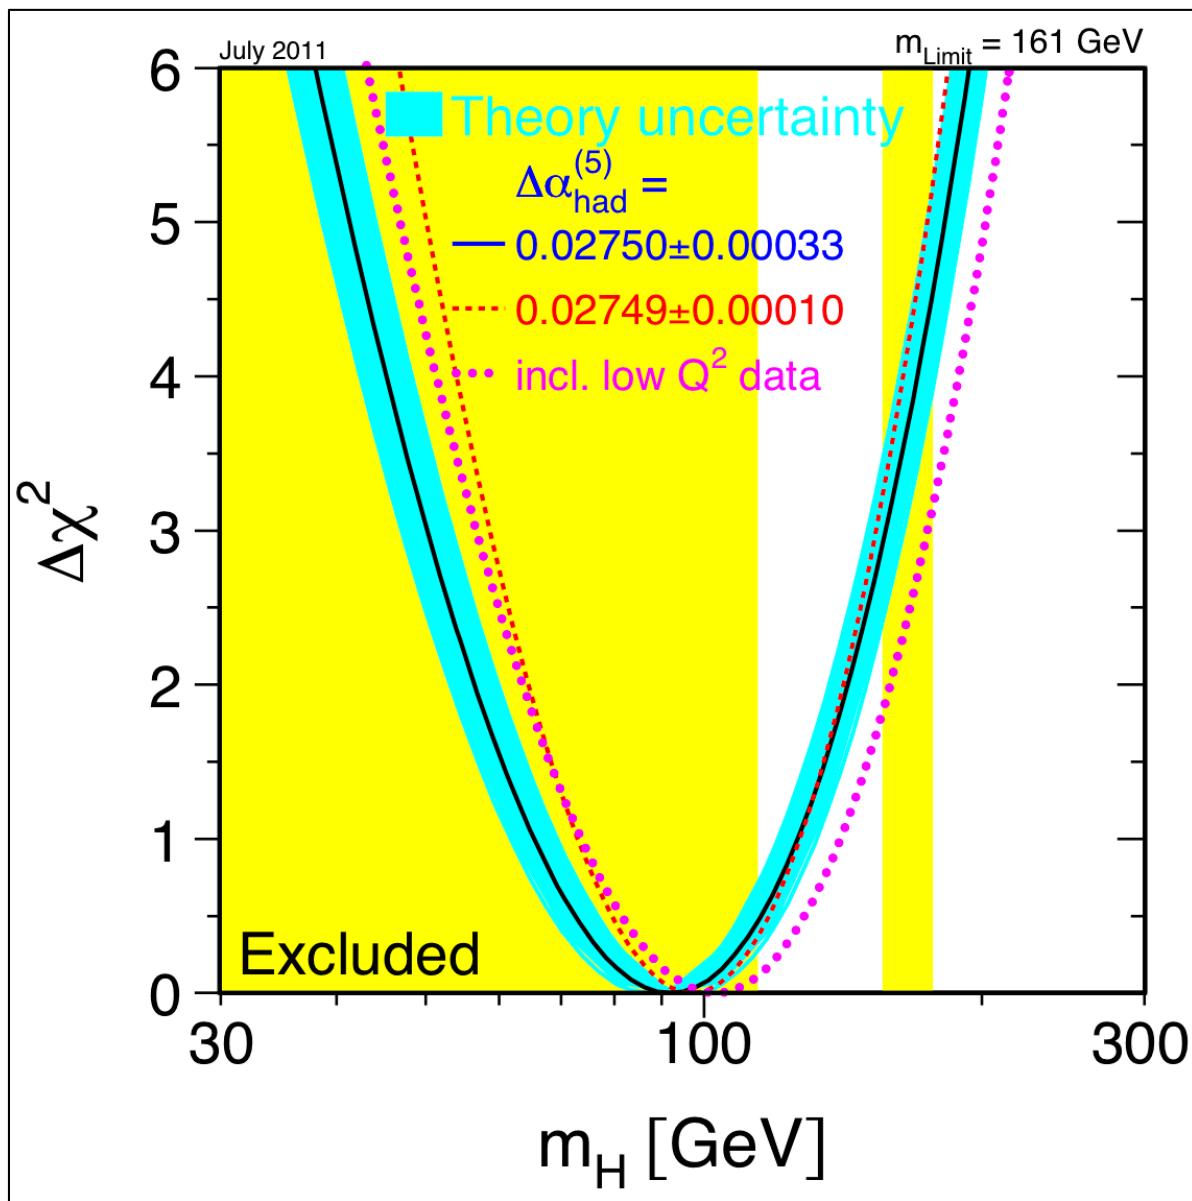

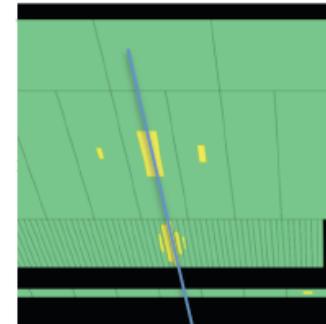

$$m_{\gamma\gamma}^2 = 2 E_1 E_2 (1 - \cos\alpha)$$

Use longitudinal segmentation of EM calorimeter to measure photon polar angle  $\theta$

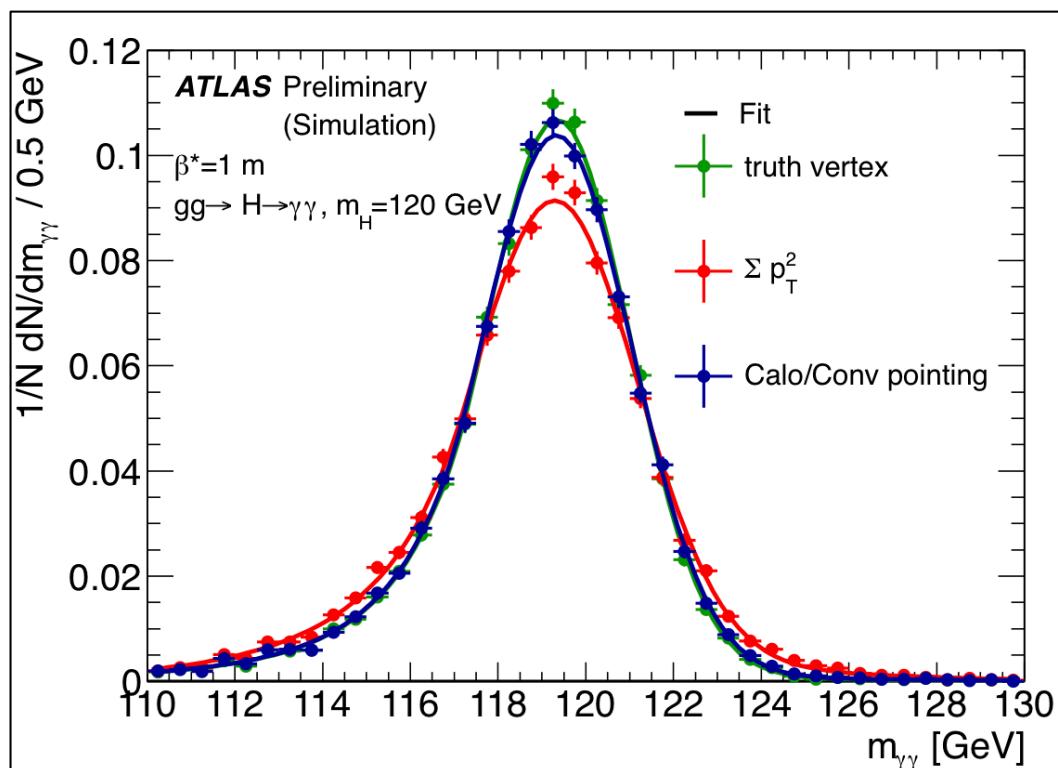

Crucial at high pile-up: many vertices distributed over  $\sigma_z$  (LHC beam spot)  $\sim 5.6$  cm  $\rightarrow$  difficult to know which one produced the  $\gamma\gamma$  pair

1.- Measure photon direction

2.- Deduce z of PV

- Calorimeter pointing capability reduces vertex uncertainty from  $\sim 5.6$  cm (LHC beam spot) to  $\sim 1.5$  cm
- Robust against pile-up  
→ Contribution to mass resolution from angular term is negligible with calo pointing ( $\gamma \rightarrow ee$  vertex also used)

Without calo-pointing the mass resolution would deteriorate by  $\sim 20\%$  when running with  $> 10$  pile-up events
